Boje (2001; 2014) and Kearney (2002) contend that the current view is of sequential single voice stories and implies excessive reliance on the hypothetical-deductive approach (akin to simplistic causal pairings). Reality emerges as fragmented retrospectives. Imposing a meaning is insufficient and inadequate, as actors need to find their own voice and make collective sense of a situation. The answer is not to develop Harvard type case studies but to rewrite stories as polyvocal tapestries enabling different perceptions, voices and interpretations to exist, thereby explaining webs of actions and interactions. What is new in this approach is the antenarrative reading which enables narrative analysis methods to be supplemented by antenarrative methods, allowing previously fragmented and personal storytelling to be interpreted as a unified whole. This focus offers

alternative discourse analysis strategies that can be applied where qualitative story analyses can help to assess subjective, yet ‘insightful’ knowledge in order to construct negotiated, ‘true’ and significant understanding of complex interactions (see for example, Drevin, 2011).

As for the longer-term future, good stories can also benefit from pictures, sound and added depth. Once we have mastered the techniques of telling complex, modern stories, we need to focus on composing that information. Even the most gripping story needs to be made attractive and believable. Textual information needs additional support not only in ‘emplotting’ and in maintaining coherence and perspective, but also in ascertaining the plausibility of constructed stories and in differentiating between noise and narrative. Developing improved techniques for organising or visualising knowledge (such as Net maps) can therefore help in untangling some of the fragmented strands and in making the stories more realistic and understandable, as well as ultimately more appealing, convincing and memorable.

CONCLUSION

IS failures are a familiar aspect of the reality and practice of software development and operation. Yet, attempts to make sense of their causes are limited by the paucity of methods capable of providing the needed insights. Improving the ability to analyse the systemic causes and their dynamic nature relies on the development of case histories that support historical research and retrospective sensemaking into the context of failure.

Stories provide a powerful research tool that can be used to reflect, share and make sense. With the benefit of hindsight it is possible to reconstruct a systematic re-telling of events that have led to a failure. The combination of case histories with narrative descriptions therefore offers richer insights. The narrated structure provides an explanation as to how and why failures occur. The purpose of the structure is to make sense of the rich tapestry of interactions and connections by

following an identified storyline that chronicles and links relevant issues within the environment. Engaging with the worlds of others through the medium of a story enables a deeper and richer reflection. Indeed, recounted life may prise open perspectives that would have been inaccessible using ordinary methods and thinking arrangements. Moreover, failure tends to highlight missing and incorrect assumptions and faulty defensive mechanisms and can therefore serve as a pretext to updating the frame of reference or the context for understanding as the listeners learn to construct a meaning and make sense of a highly multifaceted, multilayered and complex situation.

KEY TERMS AND DEFINITIONS

Antenarrative: The fragmented and messy and dynamic stories of real life in their original context before a clear narrative is developed to explain away a certain aspect.

Case History: Specialised retrospective historical research focusing on failure incidents. Case histories emphasise the background and context that can help in untangling relationships and causes thus making sense of the events leading to the failure.

Case Study: Investigation of phenomena in naturalistic setting, conducted in order to enable an in depth analysis of that phenomena.

Challenged Projects: Partially successful completed and approved projects which are late, over budget, and have fewer features and functions than originally specified. The degree of challenge depends on the way constraints are applied and interpreted within the organisation and the priorities and tolerance available in any particular area.

Failed Projects: Projects that are: cancelled before completion, are never implemented or are scrapped following installation. May also apply to projects that involve significant litigation.

Forensic Systems Engineering: Post-mortem analysis and study of failed or challenged IT processes, products, artefacts, services or projects aimed at uncovering the systemic causes, dynamics and relationships that contributed to the shortfalls or failures.

Storytelling: A method of communicating and sharing ideas, experiences and knowledge in a specific context.

The Measurement and Recognition of Intellectual Capital in the Process of Accounting Convergence Trends and Patterns

M**Ionica Oncioiu***Titu Maiorescu University, Romania*

INTRODUCTION

The value of intangible assets has been the main focus in the debates between international professionals and business world for many decades. Today, this concept interferes with the international process of assessment, but also with the convergence of accounting. The need to determine the value of these assets lies in the more virulent criticism brought to the traditional accounting system, placed face to face with an increasing vision of financial assets of a company. In an uncertain world with imperfect and incomplete markets (financial crisis), no particular measurement objective should be regarded as having a monopoly, and different measurements should be regarded as complementing one another.

The problem is how to choose the best of them in the context of satisfying accounting information users' requirements, on the one hand and complying with accounting principles and fundamentals, on the other hand.

Basically, because of different research directions, so confusion can arise regarding the use of terms: intellectual capital, intangible assets, knowledge assets (knowledge assets). Thus, the term intangible assets is used especially in financial accounting, the term is used in active knowledge economy and the term intellectual capital / human capital management is used in particular.

Sometimes the term "intellectual capital" is considered synonymous with the term "intangible assets". OECD definition of the distinction made

however, by locating intellectual capital as a subset of intangible assets rather than intangible assets of the company. As a result, there are intangible elements of nature intangible assets are not logically part of intellectual capital. For example, reputation may be the result of judicious use of intellectual capital but is not part of it.

It is an intellectual potential, consisting of knowledge in different forms, which has the ability to make technological and management processes in a number of operational items, assets, creating value, to be integrated the final products both material and immaterial of a company.

Since historically, the distinction between intangible assets and intellectual capital was initially very vague. Producers and users of financial statements consider that in the measurement and presentation of accounting information, the most widely used is the historical cost, although it has some weaknesses. This is usually combined with other bases of evaluation. Moreover, the tendency is to use current cost accounting in response to failure based on historical cost model to solve problems connected with non-cash effect of changes in asset prices.

Accountants, in their turn, reflect accounting estimates only in registers and certainly not the value generated by the presentation of materials. It is a clear dichotomy between the historical cost accounting and fair value in accounting measurement, which creates a productive tension in discussions related to economy based on knowledge. However, it is more likely for a certain period of

time to develop both paradigms in parallel and then become convergent, thus solving the paradox of intangible asset valuation.

BACKGROUND

In recent decades there was an idea almost unanimous on the growing importance of intellectual capital. It is said more often today „intellectual capital is the engine of the new economy” or „knowledge and information” is the most valuable commodity. The new economy is recognized as an economy in which companies value lies in the knowledge and skills of managers / employees rather than tangible assets value.

Also, many economists have stressed the importance of intellectual capital as a production factor in comparison with traditional assets. There are two theories on economic growth: the theory of neo-classical growth theory exogenous and endogenous growth. Intangibles reflect different endogenous model.

According to endogenous growth model of production is defined as a function dependent accumulation of immaterial (intangible). Over time, permanent growth is possible only if the intangible capital stock changes virtually forever.

Management problem that intangible asset is not new, and the problem of „intellectual capital” is the last line developed in knowledge management.

The Norwegian Government has funded a research project to develop a model of skill capital of the company, he was later involved in an ISO-type certification process that included intellectual capital.

In all these experimental projects prevailing spirit of participation rather than a theoretical development, but current area of interest in intellectual capital research includes: the creation and management of intellectual capital, understanding how best to measure intellectual capital.

Scientists Pierre and Martory (2000) are indicating that “the scientific literature and official texts do not have clear definitions for the notion

of intangible asset. Most authors prefer to make a simple list of all the main components while accounting official texts define this vague notion. In fact, the general definitions quickly become useless due to their very little analytical and more precise definitions prove to be too limited to particular cases”.

Regarding the practical need of these measurements it can be supported by an international study on measuring the importance of intellectual capital in the businesses, led by Arthur Andersen in 1998 and held within the 368 companies in Europe, North America and Asia. The results of this study can be summarized as follows:

- The majority of respondents are convinced that reports on intellectual capital will increase quantitatively;
- Almost three quarters of respondents have already tried the organizations they lead, at least two non-financial measurement models;
- The majority believes that the assessment firm’s intellectual capital can be increased based on organizational performance;

Similar studies have been done so in 1998 a study conducted by Watherhouse and Svendsen (Measuring What People Know) and conducted on a sample of 114 top managers of the largest Canadian companies found that measuring intellectual capital is considered as a basic strategic condition and the company’s management should constantly reported, as often as other non-financial measurements such as innovation, product quality, customer relationships with investors and business partners, community relations, the effects company activities on the environment. Of all these non-financial measurements, the respondents were considered the least satisfied in terms of indicators that capture the firm’s intellectual capital.

However, in the ‘90s, new methodologies for measuring expression and intellectual capital have been developed and applied, such as “Value Platform” – developed by Dow Chemical – “Intangible

Assets Monitor” from Celemi, “Value Scheme” from Skandia, etc.

According to Sveiby (2010) a variety of metrics have been created to try to evaluate levels of intellectual capital in firms, both bottom-up (assessing individual employee knowledge and adding it all up) and top-down (calculating intangible assets as a remainder from financial statements). Preferences vary, but just note that measurement is a topic that has been explored in some depth and that dozens of potential choices are available to firms looking to evaluate and then better manage their own intellectual capital.

In general these models support the idea that intellectual capital components can be summarized in three groups: human capital, organizational capital and customer capital generated, the goal being to maximize the value of the company. A new emerging research trend seeks to apply the concept of intellectual capital to the field of entrepreneurship (Diego Matricano, 2016).

CHALLENGES ACCOUNTING FOR INTELLECTUAL CAPITAL: STAKES, ADVANTAGES AND LIMITS

Intellectual capital, measured by education and training at work, he has developed. This happened the importance of intangible assets for the success of companies has increased significantly and traditional economic concepts and management proved not to be adequate. Thus, the latest economic and management studies have focused on developing tools to facilitate a better understanding and representation of intangible.

The main issue in terms of measuring systems is that it is not possible to measure social phenomena with scientific precision. Thus it tends, in the absence of appropriate tools to use traditional methods based on the figures - financial indicators or remove the real cause of the phenomenon that caused the occurrence of these intangible assets.

Measure aims to discover opportunities for cost or value creation, which are otherwise hidden in

traditional accounts. How much does the replacement of staff? What is the lesson learned when company staff interaction occurs with customers? What is the lost opportunity to create value where there is inadequate management systems knowledge? These are some questions to answer which is given by measuring intangible.

To meet new challenges, many companies, especially in Northern European countries, have focused attention on the concept of intellectual capital and the adoption of tools for classification and identification of new determinants of value. Accordingly, they began to be used and linguistic terms such as “Intangibles Report” or “Intellectual Capital Report” (designate different models of identification and presentation of intangible assets).

Frustrations expressed by the studies mentioned on the measurement of intellectual capital are interesting and suggest, on the one hand, the need for tangible measurement of intangible assets in general and particularly intellectual capital, and on the other hand, that the attempt has been made now leaves room for improvement.

Considers that, before presenting in detail the different methods of reporting and measuring intangible are used so far, it is necessary to present a general classification will serve as a basis for analysis and will facility understanding of the specificity of each method. Sveiby proposed classification is presented in 2001 and is based primarily on the dichotomy that characterizes these methods and models: orientation atomistic/holistic orientation (e.g., models that measure and/or individual is intangible that models that measure and/or is intangibles overall available to organizations). Then, starting from this basic distinction is a distinction between methods of monetary and non-monetary:

- *Monetary methods are useful in mergers, acquisitions of new companies listing on stock exchanges, comparisons made between companies in the same field of activity, moreover, the methods money have*

been developed based on accepted accounting rules so that they can be easily learned by accountants;

- *Non-monetary methods is the determination of innovation and performance management company* also may be noted that these methods have the advantage that it does not express the intangible assets in financial terms, so that they can be applied at any level of organization in non-profit, public companies, and/or organizations with social objectives.

According to these differences, results in a matrix with four categories of methods:

Cell A - Holistic and Monetary Methods: A method includes using financial models and, on the one hand provides a general representation of the intellectual capital of organization supporting a determination of their money and, on the other hand, because of the nature their very general and brief no intangible enable administration for the purposes of creating value.

Cell B - Atomistic and Monetary Methods: Using monetary methods include but are applied to individual intangible assets. However, although these methods focus on individual assets do not provide a clear vision of the organization in total intangible assets of total assets.

Cell C - Atomistic and Non-Monetary Methods: Includes non-monetary atomistic methods, among them, being found most important innovations thousand and more in line with the "atmosphere" knowledge economy. But, and this presents some weaknesses, namely that it does not allow comparisons and that are not always able to accurately reflect the value of individual intangible assets and, therefore, often based on approximations.

Cell D - Holistic Methods, Non-Monetary: It is observed that the literature does not provide such methods of measurement yet eloquent.

Another classification of the methods used so far was made all the Sveiby, based on ideas suggested by Luthy (1998) and Williams (2001), is as follows:

- **Direct Assessment of Intellectual Capital Methods (DIC):** Estimating the value in cash of intangible assets by determining the various components. After these components are identified, they can be measured directly, either individually or with a compound coefficient.
- **Market Capitalization Methods (MCM):** Calculate the difference between a company's market capitalization and shareholder equity value as the value of its intellectual capital or intangible assets.
- **Method Returns on Assets (ROA):** Average pre-tax earnings of a company for a period of time are divided by average assets of the company's tangible. The result is ROA - return on assets of the company which then compares the average of its industry. The differences multiplied by the average of tangible assets of the company to calculate the average annual earnings from intangibles. Dividing the average earnings above the cost average capital company or the interest rate, you can estimate the value of intangible assets or intellectual capital thereof.
- **Method Scores (Scorecard - SC):** Establish various components of intangible assets or intellectual capital and generate indicators or indices that are reported as scores (scorecards) or graphics. These methods are similar methods in that DIC is based on identifying components of intangible assets, but unlike, they do not consider the need for a financial estimate of the value of intangible assets.

Methods offer different advantages. Thus the actual amount that provides evaluations (\$), such as ROA and MCM, are useful in cases of merger and

acquisition and stock assessments. May be used to compare companies within the same industry and are useful to illustrate the financial value of intangible assets, feature that tends to draw attention to managers. Because they are based on counting rules long established and recognized them in different national laws or regulations can be easily communicated to the accounting profession. The disadvantage is the fact that all the terms, making money, they can be superficial.

DIC and SC methods advantages are that it can create a more complex organization in terms of health than financial metrics and ROA and MCM can be applied easily to any level of organization. Measurement is made closer to the event and so reporting can be more accurate and faster than financial measurements. Their disadvantage is that the indicators are contextual and must be adapted to each organization and each objective, which makes comparison difficult. Also, the methods are new and are not easily accepted by the companies and managers who are accustomed to seeing it only in purely financial.

From the perspective of global experience in evaluating intangibles, we can remember the following methods:

- Skandia Navigator, is probably the most well-known and analyzed intellectual capital measurement model that literature offers to date. Thanks to its innovative qualities it is considered a kind of archetype for the class of models for non-monetary atomist measuring. Among the advantages of this model are: it initiated a series of efforts toward abandoning traditional ideas about the determinants of value in organizations and bringing to the fore the possibility of measuring intangible assets; it highlights the crucial role of customer relationships in business value creation and shows how the nature of the relationship between companies and their customers changed; for the first time a great importance is attached to the contribution that can bring renewal and development of the organization's value;
- The Intangible Assets Monitor is a model that can be applied to all companies and its indicators are chosen according to the characteristics of the company, industry, competitive variables, company's history, organizational culture and company management. According to the model, intangible income can be divided into: strengthening the company's image, strengthening the organization and enhancing its competence;
- The Balanced Scorecard model that Kaplan and Norton have designed does not present a general system of indicators to measure intellectual capital, the argument being that a general system of indicators could leave out certain aspects of each company related to its objectives, processes and the context in which it operates. Traditional indicators provide information about the past performance of the company, while non-financial indicators can measure, for example, customer satisfaction, corporate innovative activities and improvements to various processes of the company. Combining the two types of indicators allows managers to obtain a balanced image on company performance. Braam (2001) points out that diffusion of innovative practices of management or management accounting, such as the Balanced Scorecard, can bring a discrepancy between the "tag" of the implemented concept and its contents. Authors such as Guthrie and Dumay (2015) have shown that this model can be used for evaluating intellectual capital. Comparison made between Balance Scorecard and intellectual capital valuation methods reveal other similarities such as recognition strategy as an essential component of performance management need to find a concise and fully expressing the company's situation, attention to intangible assets and knowledge. In other words, it is possible that some organizations only claim that they use the Balanced Scorecard, while

the implementation substance ignores the considered defining characteristics of Balanced Scorecard (connecting indicators to the strategy, causal relationships between indicators etc.). Therefore, to assess whether the Balanced Scorecard is used in practice is dependent on defining and clarifying the concept, ie the unequivocal identification of the characteristics that define a Balanced Scorecard;

- Lev's Knowledge Capital Formula Method for measuring knowledge capital is based on the traditional method for calculating goodwill. One difference is that, in Lev's model, additional revenues are replaced by residual income attributable to intangible assets. Based on these critical observations, in the scientific literature, the Value Chain Scoreboard has appeared, which is an atomistic method of measuring intangible assets which are pending completion;
- Criticism of the method Tobin's Q considered the volatility of the courses on the capital market, often beyond the control of management, which directly affect the market value of the intellectual capital of the company, and focused on the fact that this way of calculating the intellectual capital is not very robust. However, in his work, Stewart argues, by exemplifying, that both market value and book value may be diminished. Another weakness of the method is that the indicator "Q" may not be determined by the value of intangible assets;
- The Economic Value Added model was initially developed as an internal measure of performance used by managers to help them make decisions on investments. In practice, it has been demonstrated that an investment project which causes higher income than the net cost of its funding and thus generates profit, does not necessarily lead to an increased company value;

- Technology Broker stated that it is itself an intellectual asset for organizations. But the main weakness of the model is considered to be related to the possibility of transforming the qualitative results in monetary results. For example, using market-based approach is likely to not be identified on the market any information on prices of many of the elements that form the intellectual capital. Income-based approach suffers from the bias of the estimates cash-flow;
- The Weighted Patents Citation model estimates a "technological factor" to identify the impact of research-development efforts leading to the creation of intellectual property and uses indicators such as research-development expenses / sales, number of patents, income / research-development expenses, etc. "The evaluation process of patents" is an effort that involves teamwork, in which specialists interact in marketing and research-development to decide the viability of abandoning or continuing the research-development process.

Based on this overview of the different methods of measuring intellectual capital of companies, we can say that the literature and practice offer several models, each with its strengths and weaknesses. Moreover, we can see that some of the intellectual capital valuation models are built on the same principles and using the same indicators, but they are named differently. For example, Skandia Navigator uses the term "human capital", Technology Broker uses the name "people-based activities" (human-centered assets) and Intangible Assets Monitor uses "staff competence" to denote the same concept.

Andriessen and Stam (2004) on the other hand, have introduced significant changes, particularly with respect to organization. They break down each of the other IC groups between assets, investments, and effects. This approach is intuitively appealing as it provides a reading on the current stock of

intellectual capital, its impact, and its potential for the future.

There are other versions, some adding categories, but most scholars stick with the three basic categories (and virtually all research includes the three in some form) (e.g. Andreou et al., 2007). If knowledge assets are the single most valuable asset available to a firm seeking to establish sustainable competitive advantage in the marketplace, per the resource-based/knowledge-based theory of the firm, there are clear implications for corporate governance. As a result, at the intersection of intellectual capital and corporate governance is an interest in disclosure. The art of managing knowledge assets is complex and, as previously noted, the payoff may be long in coming and difficult to tie directly to investment in knowledge. While the specifics disclosure are still early in development (Abeysekera, 2006), there have been some moves toward standardization. Managers recognize the value of showing investment and interest in developing intangibles, and voluntary disclosure rectifies issues such as information agency (Cerbiom and Parboncui, 2007). Guthrie and Dumay (2015) reveals that interest in public sector and IC is alive and well and the major difference between public sector and mainstream IC research is a complete lack of normative research.

This demonstrates that the field is still at an early stage and no one wants to give up their own nomenclature borrowing aspects of the work of others, as long as it was shown that one method is generally valid. For this reason, an important aspect of research is to develop a common set of definitions and indicators that can be easily generalized.

An optimistic attitude regarding the chances of success of a development project will lead to the capitalization of development costs, with implications for the size of the result, the capitalization for the year. In future exercises, expenses recording with amortization will impact the result in the sense of decreasing it. If the enterprise has the interest payment of development costs in the

profit and loss (expenditure) it will claim that at least one of the conditions stipulated by IAS 38 para. 43 is not met.

One criticism of the procedures above concerns that they contain a certain „dose” of creative accounting with the character of subjectivity with the realization that they change the presentation of accounts, but are nonetheless the result of an option, when selected from among more methods, which makes us say that they are within the accounting regulations.

Referring to development costs, for example, their positioning on the boundary between evaluation and accountability requires the existence of a bias caused by handling interest income. If the enterprise has a policy aimed at transferring these expenses in the profit and loss (expenditure) account, we can claim that at least one of the requirements for classification as an intangible asset development costs - which would affect the balance - is not met.

The Fourth Directive states that these expenses must be charged to the profit and loss, unless national law does not provide for their capitalization. These provisions were acquired differently by the EU countries, in Germany is forbidden to capitalize these expenses. France is the opposite, considering them capitalizable and depreciable in 5 years. In Belgium, Italy and the Netherlands, the capitalization of the costs of research is questionable, the trend being the exclusion of these expenses from the asset. Development costs can both be capitalized and amortized within 5 years (Belgium and Italy) or during their useful life (the Netherlands). In Spain and the UK, research costs are non-capitalizable under certain conditions and can be amortized for a period of 5 years, respectively during the useful life.

All the measures against “fraudulent” accounting practices must have the purpose to ensure a capital accounting information on qualitative intellectual capital that faithfully represents reality and to allow decisions to ensure an optimal allocation between participants in value creation.

FUTURE RESEARCH DIRECTIONS

Therefore, their representation in situations of intellectual capital value as intangible asset, to a value as close as possible to the real one, is essential for users since they ground their decisions based on its level.

Moreover, the success of any company depends not least on whether the intellectual capital has recognized the important role of an examination over several years of the development of intangible values both in the construction of the house of intangible values and the annual evaluation, and if it has implemented this knowledge consistently in everyday decisions.

The author believes that due to the high influence, both positively and negatively, of the intellectual capital on its value is necessary for conducting more detailed studies of diagnostic analysis to identify and measure them, and also to determine a set of evaluation methods that leads to a correct result, close to the market.

Of course, the appeal to intangible resources in order to create value remains a significant challenge for specialists because the country's competitive advantage should be interpreted in relation to the skills, talent and intellectual capital stock. Future research efforts of SMEs should turn those scales into operational parameters and promote the development of empirical methodological studies based on dialogue and the dissemination of knowledge and experience in interdisciplinary research teams.

CONCLUSION

Companies have recognized the importance of intellectual capital as a key factor for success, looking for ways to measure and control this factor. Financial performance measurement is not sufficient that reflects how the profit is due to

intellectual capital. In the knowledge economy, wealth is created through a combination of services and products that generate value. Each company has its unique set of knowledge, skills, values and solutions, all intangible resources. Monitoring and management of these resources can be made with value creation efficiency analysis because it is a priority for managers to obtain and maintain productivity and efficiency in the enterprise.

Another aspect that can be observed is related to the fact that some researchers have developed theories based on reflection the results of case studies, others have developed some indicators that have applied in practice (as in the case of Skandia, for example) but without testing their validity in advance and others have developed sets of indicators were not tested. For this reason another challenge in the study of intellectual capital is the need for researchers to base their conclusions on several empirical researches. And, to make conclusive statements about intellectual capital, we need to consider that a coherent field theory has positive effects in multiple areas such as accounting, human resources, finance, strategic management, etc.

Very important is that those who investigate aspects of intellectual capital to set realistic goals. As with many challenges, such as efforts to conceptualization of the field, trying to measure intellectual capital; setting causal relations - effect, demonstrating the accuracy of proxies, it happens that many companies have an intellectual capital management system its use in some individual indicators whose relevance is not fully justified.

It is therefore important to determine and establish relevant indicators, the group of them in specific categories (quantitative or qualitative aspects related to individual company's business - e.g. employees - or macro issues) and not I just put together, and also to assign each category a specific weight in calculating the final result.

KEY TERMS AND DEFINITIONS

Assets: As future economic benefits controlled by a particular business entity and also as economic resources which are owned by a business.

Estimate: Opinion regarding the value.

Intangible: Represent immaterial assets.

Valuation: The process of determining the value of an asset.

Project Control Using a Bayesian Approach

Franco Caron

Politecnico di Milano, Italy

INTRODUCTION

Forecasting is a critical activity in project management: relying upon sound estimates to complete, the project manager can steer the ongoing project in order to meet specific time and cost objectives (Dvir and Lechler, 2004). Moreover, foresight is needed to avoid constantly being forced to manage emergencies, since emergency implies a reactive action. Without anticipation there can be no rationale in making a decision and what we can do is just to be adaptable to changing circumstances.

Planning and forecasting are strictly intertwined both in the early stage when the project baseline must be determined and throughout the entire project life cycle when the project baseline has to be followed (Hogarth and Makridakis, 1981). Forecasting feeds (re)planning (corrective measures are taken based on forecast) and (re)planning feeds forecasting (corrective measures will influence the future).

In the project control process the role of the Estimate to Complete (ETC) is critical, since the information drawn from the ETC, compared with the project baseline, should highlight the need for and the type of corrective action that may improve the project performance. In fact, ETC is the base for any effective corrective action. This approach to project control corresponds to a *feed-forward* type control loop (Anbari, 2003; Christensen, 1996), since the forecast informs present-day decisions.

From a recent survey (Morrow, 2011), analyzing the data of more than 300 global mega-projects, it appeared that in 2010 65% of the industrial projects with a minimum budget of 1 billion US dollars did not succeed in meeting the objectives of cost, duration and quality. However, it remains an open question whether these failures are due to

a poor performance during the execution stage or to a lack of forecasting accuracy during the planning and control process. In the former case, both positive and negative deviations from the project baseline should be expected. On the contrary, a systematic overrun in terms of cost and/or time may be easier explained as a weakness in the forecasting process since the beginning of the project. As a consequence, the forecasting process plays a critical role.

To explain the accuracy of the forecasting process, some considerations must be developed about the knowledge sources feeding the process, the forecasting techniques to be applied and the mitigating measures taken in order to avoid possible biases affecting the forecasting process.

As shown in Figure 1, at a given time of the project duration, i.e. the time now (TN), a certain amount of the work will be already completed (Work Completed, WC), while the rest of the work will be ahead, corresponding to the Work Remaining (WR). The cost and time performance related to the Work Completed will be known, while a forecast will have to be developed for the WR.

It should be noted that both the *accuracy of the forecast about WR* and the *impact of the corrective actions* that may be implemented based on the forecast depend on the progress of the project at the Time Now. The effectiveness of the corrective actions is greater in the early stages of the project execution and progressively diminishes while progress increases: in fact, as progress increases, the degrees of freedom available to steer the project tend to reduce progressively. On the other hand, the capability to forecast the project final duration and the final cost follows an opposite trend. In fact, at an early time in the execution phase, the knowledge available to the decision maker is

DOI: 10.4018/978-1-5225-2255-3.ch493

Figure 1. Estimation at completion at time now (internal view)

scant and rapidly evolving; therefore, the capability to provide a *reliable forecast* is jeopardized, particularly if the forecast is based only upon the knowledge related to the ongoing project.

Drawing on a set of case studies (Caron et al., 2013a; Caron et al. 2013b, Caron et al., 2016), this paper proposes a Bayesian approach to determine the estimate to complete for a project. The paper has a twofold objective:

- To identify all the available knowledge in order to improve the forecasting process;
- To develop a Bayesian approach in order to integrate in a formal and rigorous way the diverse knowledge sources.

The second section analyzes the different knowledge sources available; the third section addresses the issue of possible bias during the forecasting process; the fourth section introduces the Earned Value Management approach frequently used to determine the estimate at completion for a project, both in terms of cost and time; the fifth section introduces the general structure of a Bayesian model and eventually some results are given stemming from the application of the model to some projects in the oil and gas industry.

BACKGROUND

As mentioned above, all the knowledge available should be used in order to address the planning and

control process for a complex project (Caron, 2014; Reich et al., 2014; Schindler and Eppler, 2003).

In general, the knowledge available to the project team may be classified in two ways: explicit/ tacit and internal/external. Explicit external knowledge corresponds to data records about projects completed in the past, including measures of forecasting capability in terms of the difference between estimated and actual final cost and duration. Taking into consideration past experience should mitigate possible “optimistic” bias in estimating future project performance (Lovallo and Kahneman, 2003). Explicit internal knowledge corresponds to data records concerning the work completed WC, allowing for an evaluation of project performance at Time Now. Tacit external knowledge concerns the similarities between the current project and some past projects in order to transfer past data to the current project. Tacit internal project is about possible events/situations affecting the project’s work remaining.

In fact, relying only on data records related to WC while developing a forecast could be misleading, since it would be similar to driving a car whilst looking just in the rear view mirror, so making it impossible to dodge the obstacles that may lie on the route ahead. It should be noted that the contribution deriving from the data records to the estimate at completion may be considered reliable just for the near future and losing progressively accurateness if a more extended horizon is considered. Since the reliability of the estimation based just on data records rapidly decreases, so the

contribution deriving from the subjective information expressed through experts' opinions becomes predominant, particularly at the project outset.

In general, the specific contribution given by tacit knowledge i.e. by experts about the future development of the project, may concern:

- Hindsight, i.e. monitoring drivers explaining the project development during WC, and presumably affecting also WR, e.g. answering the question what kind of plausible drivers may have generated the actual development of the project till the Time Now and how they will also influence the future? (e.g. drivers such as schedule aggressiveness, degree of engineering completeness, owner involvement, turnover in project leadership, anomalous low bid from subcontractors, unsatisfied stakeholders, new technology, project team integration, project team staffing, etc.).
- Insight, i.e. making sense of the weak signals that anticipate the emerging situations possibly affecting project performance (e.g. weak signals such as frequent scope changes, permits delay, engineering sequence not aligned with construction, high rate of rework in construction, missing data in design process, etc.) (Williams et al., 2012; Haji-Kazemi et al., 2013).
- Foresight, i.e. anticipating certain/uncertain events or conditions affecting project performance during WR which may originate both internally and externally to the project. Certain events may include planned corrective actions or contractual constraints, while uncertain events, i.e. risks, may arise both in terms of threats (e.g. adverse weather conditions) and opportunities (e.g. more efficient solutions deriving from suppliers' collaboration).

The final objective of this chapter is to develop a Bayesian approach integrating the knowledge contribution deriving from different sources, i.e.

data records related to the ongoing project, experts' judgment about the expected performance during WR and data records deriving from similar projects completed in the past.

FORECASTING BIAS

The knowledge contribution given by external knowledge related to similar projects completed in the past allows for stabilizing the forecast throughout the project life cycle, by making the forecast less sensitive to performance variability in particular at the project outset, and mitigating any possible bias effect on the forecast.

As for forecasting bias, Kahneman's and Tversky's studies (1979) showed that a major source of forecasting failure, which influences the accuracy of final cost and duration estimates, is linked to an exclusively "*internal*" view of the project, i.e. based only on knowledge deriving from inside the ongoing project. As a consequence, the research focus has moved to the psychological and political factors affecting the project planning process (Lovallo & Kahneman, 2003), and, in particular, two main sources of planning failure have been pointed out (Flyvbjerg, 2006; Flyvbjerg, 2009).

Firstly, the *cognitive bias* (availability, representativeness, anchoring and adjustment, etc.) normally generating over-optimism, i.e. the common attitude to assess future projects with greater optimism than justified by the actual previous experience. Secondly, the *strategic and political pressures*, that may typically emerge during proposal preparation. Indeed, the approval of a project pre-supposes a competition involving different proposals, which often causes a voluntary underestimation of cost and duration by the project proposers in order to make their own proposal as attractive as possible.

Even more so, the need emerges to exploit all the available knowledge during the planning process, in order to minimize any bias effect. In fact, as shown in Figure 2, the traditional control process often focuses only on data related to the

Figure 2. Internal and external view

current project, corresponding to an exclusively “internal” view (Flyvbjerg, 2006). An integration is needed between the “internal” and the “external” view, where the latter is based on knowledge related to the past experience (see Figure 2) (Flyvbjerg, 2006).

In fact, the current project can be viewed as belonging to a cluster of similar projects completed in the past. Note that the selection of the cluster of similar projects is basically subjective since it depends on the similarity criteria adopted (Green & Armstrong, 2007). Some cases, in fact, may express strong ambiguity. For example, if a company has to estimate the cost of an investment in a new technology and in an unfamiliar technological domain, should it take into account the set of highly innovative projects developed in different technological domains or the set of barely innovative projects but belonging to the same technological domain? Neither the former nor the latter option may be the best solution but both should be considered and weighted (Kahneman & Tversky, 1979). Besides similarity criteria, the subjective assessment should also consider the trade-off between using a large number of past projects, leading to the risk of including projects substantially different from the current one, and a small number of projects, leading to the risk of losing statistic significance. Also the transfer-

ability of past data to the current project and the possible presence of outliers in the distribution should be critically evaluated.

EARNED VALUE MANAGEMENT SYSTEM

The future is something having its seeds in the present (and in the past) (Kuosa, 2012). This is the basis for the forecasting process. In general, different approaches are available in order to implement the forecasting process during project control (trend analysis, pattern analysis, simulation, etc.). In particular, in project management Trend Analysis has become very popular. Trend Analysis is based on the extrapolation into the future, i.e. into the WR, of the actual trend at Time Now of a performance index, e.g. Cost Performance Index (CPI) and Schedule Performance Index (SPI), related to WC. This is the traditional approach applied in the Earned Value Management, representing a very popular methodology used to develop an estimate at completion for the project (Fleming and Koppelman, 2006).

As Project Management Institute (2013) stated, the main processes involved in project management are: initiating, planning, executing, monitoring, controlling and closing. In particular, Earned

Value Management (EVM) represents an effective way of addressing the project control process. EVM is an efficient performance measurement and reporting technique for estimating cost and time at completion (Project Management Institute, 2013; Marshall et al., 2008). The following basic parameters are used in EVM, where TN indicates Time Now, i.e. the time along the project life cycle at which the control process is implemented:

- Planned Value (PV), the budget cost of work scheduled at TN;
- Earned Value (EV), the budget cost of work completed at TN;
- Actual Cost (AC), the actual cost of work completed at TN.

EVM was improved by Lipke (2002_a; 2000_b; 2003), who introduced the concept of Earned Schedule (ES) for obtaining a measure of the schedule performance index based on time units and overcoming the flaws associated with a Schedule Performance Index SPI defined as the ratio between EV and PV, both of them expressed in monetary terms. Earned Schedule is the time at which the EV value achieved at TN should have been obtained according to the project baseline. The new Schedule Performance Index SPI(t) at TN, defined as the ratio between ES and TN, represents a more effective approach, since it avoids the problem of the convergence of the EV and PV values toward BAC, i.e. Budget at Completion, as the project reaches completion (Lipke, 2006_a; Lipke, 2006_b).

The above three parameters and the ES, all of them evaluated at TN, allow for the calculation of a set of indices and variances at TN. The most important of these are:

- Cost Performance Index:

$$CPI = EV / AC$$

- Cost Variance:

$$CV = EV - AC$$

- Schedule Performance Index:

$$SPI_{(t)} = ES / TN;$$

- Schedule Variance:

$$SV_{(t)} = ES - TN$$

Variances CV and SV(t) summarize the project's past performance during WC, while indexes CPI and SPI(t) may be used in order to extrapolate the current trend into the future and estimate the future performance during WR (Anbari, 2003).

Many Estimate at Completion formulas have been proposed during almost 50 years of EVM application but none of them has proved to be always more accurate than any other one (Christensen, 1993). In the basic approach, the estimations of final cost (i.e. EAC) and final duration (i.e. TAC, Time at Completion) are based on the following equations:

$$EAC = AC + (BAC - EV) / CPI_f \quad (1)$$

where:

AC = Actual Cost at TN;

BAC = Budget at Completion;

EV = Earned Value at TN;

CPI_f = Cost Performance Index estimated for the work remaining (WR).

$$TAC = TN + (PAC - ES) / SPI_f \quad (2)$$

where:

TN = Time Now;

PAC = Planned at Completion, i.e. the planned duration of the project;

ES = Earned Schedule at Time Now;

SPI_f = Schedule Performance Index estimated for the work remaining (WR).

It should be noted that future performance may significantly differ from past performance. The new performance indices CPI_f and $SPI(t)_f$ have

been introduced in equations 1 and 2 with reference to the Work Remaining and may consider a possible evolution of the project different from the expected, in particular in terms of performance. While the generic indices CPI and SPI(t) are related to the overall WC, CPI_f and $SPI_{(t)f}$ will be related to the overall WR. In fact, relying only on past performance while developing a forecast could be misleading.

Both equations 1 and 2 indicate that the values assigned to the performance indexes CPI_f and SPI_f play a critical role in order to obtain an accurate estimate of the final cost and duration. As a consequence, forecasting capability can be improved by utilizing all the available knowledge about the performance indexes CPI_f and SPI_f (Liu & Zu, 2007; Goodwin, 2005). The Bayesian approach allows for integrating in a rigorous way the knowledge content stemming from diverse knowledge sources.

BAYESIAN APPROACH

The Bayes Theorem represents a rigorous and formal approach allowing for an update of a prior estimate, which expresses the experts' preliminary opinion, by means of the data gathered in the field. For instance, the project team may assume a prior estimate of the final budget overrun, based on subjective expectations about the development of the ongoing project, and this prior estimate may be updated based on the actual performance of the current project at Time Now (Caron et al., 2013). It should be noted that the two knowledge sources should be considered independently, so avoiding any anchoring bias. In this way knowledge stemming from two different sources, data records and expert's judgment, can be integrated. In a Bayesian framework, the experts' preliminary opinions, are an example of use of subjective probability, the only probability concept applicable to non-repetitive processes such as the projects. Subjective probability is defined as the degree of belief in

the occurrence of an event, by a given person at a given time and with a given set of information. It should be noted that increasing the level of knowledge available may modify the value of the subjective probability assigned to a future event (De Finetti, 1937; Caron and al., 2013). While the metaphor of 'frequency based' probability is the dice throwing (i.e. a repetitive process), the metaphor of the subjective probability is the bet (i.e. a unique process). In general, we can assume that any proactive action involving the future is similar to a bet. In fact, De Finetti defined probability as a price. Let's consider a gamble where if the event E occurs the better wins 1, if it doesn't happen the better wins 0. How much is the better prepared to pay for accepting the gamble? That price corresponds to the subjective probability value associated to the event E. The probability value corresponds to the degree of belief about event E occurring.

The essence of Bayesian inference is using probability to describe our state of knowledge about some event or parameter of interest. A prior distribution (based on expert's tacit knowledge) is updated by means of experimental observations (data records) collected during the execution process, in order to obtain a posterior distribution, integrating both knowledge types.

For instance, the project team may assume a prior distribution of the final budget overrun, based on subjective expectations about the development of the current project, and this prior distribution may be updated based on the actual performance of the current project until Time Now (Caron et al., 2013).

Hence, Bayesian approaches to formulate valid forecasts have been proposed in literature (Palomo et al., 2006; Gardoni et al., 2007; Kim and Reinschmidt, 2009). The adoption of a Bayesian approach enables the elaboration of probabilistic time and cost estimates at completion based on multiple knowledge sources. This statement is easier to understand if the formulation of the Bayesian theorem is considered:

$$f(\mu | y_1, y_2, \dots, y_n) \propto L(\mu; y_1, y_2, \dots, y_n) \cdot f(\mu) \quad (3)$$

Eq. (3) consists of three main components:

- $f(\mu)$ is the prior distribution of the parameter of inference, μ : it summarizes the initial subjective opinion detained by the decision-maker about the probability density function of the parameter μ ;
- $L(\mu; y_1, y_2, \dots, y_n)$ is the likelihood function, obtained after the collection of the n experimental data $y_1, y_2, \dots, y_n$;
- $f(\mu | y_1, y_2, \dots, y_n)$ is the posterior distribution, i.e. the distribution that expresses the knowledge acquired about the parameter μ after updating the initial subjective judgments with the experimental data.

CASE STUDIES

Firstly, the Bayesian approach requires the definition of the inference parameter, for instance the performance indices CPI_f and $SPI(t)_f$ in order to forecast the final variance between budget cost and actual cost (or between scheduled duration and actual duration). Secondly, it requires the definition of the prior and likelihood distributions in order to obtain the posterior distribution. The prior distribution is based on the elicitation of the experts' tacit knowledge. It may be integrated by the data records related to projects completed in the past. The likelihood distribution is based on data records related to the ongoing project. The Bayesian approach allows for the integration of the diverse knowledge sources. The prior distribution updated by the likelihood function gives the posterior distribution. It should be noted that the Bayesian approach doesn't offer a point estimate, such as in the traditional EVM approach, but a distribution estimate, so increasing the knowledge available for the project team. Moving from the

prior distribution to the posterior distribution the degree of belief in the estimate increases, since a larger knowledge content has been used. Assuming that a standard distribution, e.g. a normal distribution, has been used, this improvement corresponds to a reduction of the standard deviation of the posterior distribution compared with the prior one.

An advanced Bayesian model has been applied to a set of large engineering projects in the oil and gas industry (Caron et al. 2013a; Caron et al. 2013b; Caron et al. 2016) in order to forecast the actual final duration and the actual final cost. The model utilizes three different knowledge sources: data records related to the ongoing project (indicating the actual performance trend during WC), experts' judgment about the ongoing project (looking forward to foreseeable events during WR) and data records about similar projects developed in the past (stabilizing the forecast during the project life cycle and mitigating a possible bias).

Assuming the final cost (or duration) as the inference parameter, the sequence of steps required to implement the model are:

- Determine the distribution of experts' opinions;
- Determine the distribution of similar past projects;
- Define a suitable value for the weight of the two knowledge sources included in the prior distribution;
- Determine the prior distribution;
- Determine the likelihood function;
- Obtain the posterior distribution.

The prior distribution is a summary of the initial knowledge available to the decision-maker for the forecasting process. In this model, the project team can rely on two main information sources: experts' opinions about possible events occurring in WR and data records related to similar projects completed in the past. By integrating these two components, a starting assumption about the distribution of the inference parameter (e.g. budget overrun or completion delay) can be formulated.

In order to translate these concepts in Bayesian terms, firstly two distributions have to be defined: one representing the experts' opinions and one the cluster of similar past projects. Note that the two components of the prior distribution have a subjective nature since the similarity criteria applied to past projects and the forecast of future event are based on experts' judgment.

A unique distribution has to be derived by the integration of these two components. In mathematical terms, the integration can be obtained by the concept of *mixture*: assigning a value ranging from 0 to 1 to a weight ε , the prior distribution is obtained as the weighted sum of the distribution of experts' opinions and the distribution of the cluster of similar projects:

$$\Pi(\cdot) = \varepsilon \Pi_E(\cdot) + (1 - \varepsilon) \Pi_S(\cdot) \quad (8)$$

In Equation (8):

- $\cdot$ is a generic point of the prior distribution;
- $\Pi_E(\cdot)$ is the evaluation of the distribution of experts' opinions in a generic point;
- $\Pi_S(\cdot)$ is the evaluation of the distribution of the cluster of similar projects in a generic point;
- ε is the weight.

Adjusting the value assigned to the weight ε it is possible to give more or less weighting to one of the two informative sources. When ε increases, the weight of the experts' distribution increases, while the weight of the distribution of similar projects decreases. Consequently, the prior distribution is characterized by a high level of flexibility, since it can be adapted to the project features.

As for the likelihood function, the experimental data collection will be represented by a single observation of the performance index at the Time Now. The posterior function is a mixture of the posterior distribution of similar projects and the posterior distribution of experts' opinions through the posterior weight ε^* .

Table 1. Comparison of the mean squared error

Mean Squared Error	Bayesian Model	EVM
MSE Cost	$1.23 \cdot 10^{-2}$	0.1683
MSE Time	$9.3 \cdot 10^{-3}$	$3.55 \cdot 10^{-2}$

In order to compare the Bayesian approach and the traditional EVM approach, a set of large projects related to the Oil&Gas industry have been analyzed in detail. These projects were characterized by a high level of uncertainty and complexity. After the projects reached completion, the forecasting error related to the Bayesian model were compared with the one that would have been obtained if traditional EVM forecasting formulas had been applied. The result was that the Bayesian approach allowed for a better forecasting accuracy independently from the type of project (on shore, off shore, subsea) and in particular since the early stage of the project when the information is scant and the potential impact of decisions is very high.

Eventually, it was possible to check the error made by the Bayesian model and to compare it with the one that would have been made if traditional EVM forecasting formulas had been applied. Table 1 shows the mean squared error made by the Bayesian Model and by EVM in the three Oil and Gas cases.

It is clear that the Bayesian model is more accurate: its mean squared error is ten times lower, both for cost and time performance, due to the larger amount of information used, even though the model was tested on very complex and risky projects.

FUTURE RESEARCH DIRECTIONS

Two problems have to be addressed: the elicitation of tacit knowledge by interviewing the experts, possibly avoiding cognitive and relational bias, and the extension of the application of the model to other industries.

CONCLUSION

Drawing on a set of case studies, this paper proposes a Bayesian approach to determine the estimate to complete, both in terms of cost and time, for a complex project. The paper focuses on the knowledge sources necessary to feed the forecasting process and the mitigating measures taken in order to avoid possible estimating biases affecting the process.

The Bayesian approach allows for increasing the forecasting accuracy, mainly in those fields where projects are denoted by a high degree of complexity and uncertainty and in particular in the early phase of the project when knowledge available is scant and rapidly evolving.

Eventually, a Bayesian model has been proposed allowing for integrating a multiple set of knowledge sources. The project team may assume a prior estimate of the final budget overrun, based both on subjective expectations about the current project and data records related to similar past projects, and this prior estimate may be updated based on the actual performance of the current project at Time Now, obtaining a high level of accuracy in forecasting the final cost and duration of the project.

KEY TERMS AND DEFINITIONS

Bayes Theorem: Represents a rigorous approach to update a prior distribution, which expresses the experts' preliminary opinion, through the experimental data gathered on the field.

Earned Value Management System (EVMS): Management system aiming at an integrated control of project cost and schedule based on the concept of earned value i.e. budget cost of work performed at Time Now.

Estimate to Complete (ETC): Effort required to complete the project, in terms of cost and time

Monte Carlo Simulation: “What if” analysis of the future project scenarios, provided a mathematical/logical model of the project implemented on a computer.

Project Control: Project management process aiming at identifying and implementing possible corrective actions based on the expected performance of the project.

Subjective Probability: The degree of belief in the occurrence of an event, by a given person at a given time and with a given set of information.

Trend Analysis: Linear extrapolation to the work remaining of the data records related to indices of project performance, e.g. productivity, during the execution of the work completed in order to estimate cost and time to complete the project.

Shaping Mega–Science Projects and Practical Steps for Success

Phil Crosby

Curtin University, Australia

INTRODUCTION

Success and failure in projects is a topic frequently discussed among project management (PM) practitioners. Public funded mega-scale projects especially are scrutinised for performance by funders, users, and the popular press. While a good number of notable mega-projects are delivered within acceptable parameters of time, budget and scope, many large complex projects - especially those underpinned by, or delivering, new technology - too often fail in one or more success dimension (Hartman and Ashrafi, 2004; Ellis, 2008; MoD, 2009; Brouwer, 2011; Flyvbjerg and Budzier, 2014). Perhaps of most concern is that we don't seem to be learning. Large complex projects continue to underperform despite increased availability of systemic, disciplined PM approaches, training, and internet based resources (Archibald, 2003; Flyvbjerg, Bruzelius, & Rothengatter, 2003).

Much has been written regarding project performance, and the literature contains casework and empirical studies of tens, and sometimes hundreds, of projects in an effort to distil factors governing their success or failure (e.g. Pinto and Slevin, 1989; Müller and Turner, 2007; Ika, 2009). Flyvbjerg et al. (2003) identify a 'megaproject performance paradox' that, put simply, means that despite increasing opportunities to learn by experience, project risks remain unacknowledged or unaddressed by stakeholders, and that project performance continues to disappoint.

However, the focus of this chapter is not on causes of failure, but factors underpinning success. The objective is to bring together key findings from the author's research and casework, augmented

by recent reports and lessons learned, to identify strategic activities and/or actions at the project formation phase that show strong correlation to successful project outcomes. In this chapter, mega-projects are generally defined as having hundreds of millions or even billion dollar budgets, time-frames measured in several years, and often attracting public and/or political attention. Such projects generally involve a significant information technology (IT) or software component, application of leading edge science/engineering technologies, and complexities that test traditional, rational PM methodologies.

BACKGROUND

As high-technology (high-tech) projects have grown in size, cost and risk, so has the challenge in realising success. Between the 1960's and 1980's project success emphasised delivery against the "iron triangle" (time, cost, scope). By year 2000, success criteria had expanded to include client satisfaction and stakeholder benefits. The 21st century has seen the focus broaden to embrace business success and strategic objectives (Ika, 2009).

Systematic project management emerged in the 1950s with the Program Evaluation and Review Technique (PERT), and the Critical Path Method (CPM). These methodologies continued to proliferate through the 1960s and 1970s; later becoming computerised. By 1990, PM was effectively professionalised and managed through hierarchical organisational structures, along with their attending bureaucracies, linear mode planning tools, and standardised forms of project review.

Figure 1. Project cost control performance over last 90 years
Adapted from Flyvbjerg et al., 2003.

The application of skills and techniques to meet the demands of increasing complexity and the parameters by which modern project success is measured, has lagged. Whereas moderately scaled high-tech projects can be managed using traditional PM methods and tools, the reported poor performance of many mega-projects is compelling evidence that lessons are not being learned, and that advanced PM theory and practice is not being applied (Turner, 2004; Cooke-Davies, 2002; Grün, 2004; Shenhar and Dvir, 2007). An example of this is illustrated in data by Flyvbjerg et al., (2003). See Figure 1.

The topic of mega-project management, with its inherent new scale challenges, is receiving attention by researchers, with a growing awareness of the importance of front-end planning. Difficulties with dependence on early stage risk assessment amid uncertainty are examined by Flyvbjerg et al. (2003); Bakker, Cambre, Korlaar, & Raab (2010); and Geraldi, Lee-Kelley, & Kutsch (2010). Project shaping as a management craft

is investigated by Smith and Winter (2010) who show clear links to project success, while project shaping as a competitive advantage is addressed by Miller and Lessard (2000). Blanchard (1990) and Cook-Davies (2002) each discuss the people aspects of new projects and the pivotal role of management, while work by Jani (2010) asserts that self-efficacy enables resilience in complex IT project teams. Crosby's in-depth study (2012a) reveals new attitudinal and conditional factors for shaping of complex projects specifically. Early stage critical success factors (CSF) are noted by Elenbaas (2000) who signals the crucial conditions and complex environments within project start-ups. Much referenced PM authors Shenhar and Dvir (2007) emphasise the need for early tailoring of project success measures and dimensions. Engwall and Westling (2001) explore assumptions around linear project processes and the limiting effects of articulating imperfect knowledge at project start-up. Weston (2007), Fellows and Alexander (2010), and Fisher (2010) each touch

Table 1. List of case study projects and organisations¹

Project Acronym	Location	Description
ALMA	Northern Chile	Radio telescope array of ~66 dishes.
ASKAP	Mid-West of Western Australia	Radio telescope array of 36 dishes, and precursor for the SKA project.
ATCA	Northern NSW, Australia	Radio telescope array of 6 dishes completed in 1988.
HIPER	Site not yet decided.	High power laser-driven fusion experiment.
ILC (DESY) XFEL (DESY)	Site not yet decided. Hamburg, Germany	Dual opposing linear colliders of super high power. X-Ray high power free electron laser
ITER	Provence, France.	Thermonuclear experimental reactor.
LHC	Beneath the French-Swiss border.	Large Hadron Collider – a gigantic particle accelerator.
LIDAR	Davis Station, Antarctica.	Light detection and ranging instrument configured to probe the mesosphere.
LOFAR	Centered in Northern Netherlands	Radio telescope consisting of thousands of omni-directional dipole antennas.
MeerKAT	Northern Cape of South Africa.	Radio telescope array of 7 dishes (to be expanded to ~64), and an SKA precursor.
OPAL	South of Sydney, Australia.	20 Mega-watt open-pool research reactor.
SKA	Split between Africa and Australasia.	Giant radio telescope with up to 1 million square metres of collecting area.
SYNCH (Australian Synchrotron)	Melbourne, Australia.	A particle accelerator accommodating 30 beamlines.
TOPSAT	RAL (UK). TOPSAT is still in earth orbit	A micro-satellite with advanced, down-looking, imaging cameras.
VISTA	Northern Chile	A visible and infra-red survey telescope.

on early stage risk of immature technologies. An extensive statistical study of industrial mega-projects by Merrow (2011) compellingly points to Front End Loading (FEL) as the most critical phase for driving project success.

Complementing the literature sources for this chapter are data and narratives gathered by the author from 16 large scientific facility projects in Europe, Chile and Australia. The projects were mostly selected from contemporary big astro, nuclear, and particle physics machines. Each project is characterised by having specialised infrastructure supporting new technology, >US\$100 million budget, and a challenging IT requirement. The author observed first-hand the planning and execution processes, and formal and ad-hoc meetings, both in the project office and the worksite. At each project, between five and ten formal interviews with project directors and managers

were held, each loosely structured to gather the ‘lived experiences’ of project practitioners. The fieldwork study list is shown in Table 1. Further insights were gained at relevant conferences and workshops including NASA’s annual 2009 and 2010 Project Management Challenge event.

RESEARCH FOCUS AND FINDINGS

A consistent view expressed in both the literature, and in fieldwork narratives, is that project success is not indeterminate by nature. By undertaking certain activities, coupled with setting of particular policies and launch conditions at the front-end; a project can be shaped for robustness and success (Archibald (2003). This shaping phase has a profound effect on project stabilisation, and the challenges will be different for each mega-project.

Table 2. Selected success drivers by relative importance

ID ² Ref	Success Driver	All Project Ranking	High-Tech Ranking
B	Clear project definition, requirements framed, goals, objectives, scope, success criteria, and project mission defined; sound business case established.	23.72	19.53
E	Project baseline, realistic (benchmarked) estimates, project phasing, effective project performance reviews, mission assurance systems, and measurement standards.	7.85	8.96
H	PM/Organisational understanding & competence in complex project management (beyond PMBOK level).	3.17	3.37
J	Aligned perceptions of realistic project goals & success (management and teams); sense of urgency instilled.	2.31	2.37
K	Effective stakeholder partnerships/alliances including processes for funding, contracting, and communications).	2.31	2.37
N	Understanding & continuous management of known and unknown risk exposure; maintenance and visibility of risk register.	0.91	1.13
P	Effective means of learning from analogous experience, and continuous improvement environment	0.66	0.78

Derived from findings in Crosby (2012b).

Merrow (2011) holds that turbulence and disruption are more likely a feature of poor shaping than of project management.

The author's previous meta-study (Crosby, 2012b) draws on mega-project casework and literature material from the previous four decades, to ask: what are the key strategic areas that show strong correlation to project success? The full method and results are not repeated here; suffice to say that this scientific study comprised rigorous casework using Yin's (2009) methodological approach to validating complex phenomena, which was contrasted against findings from 29 studies encompassing 2,820 projects. A sub-set of 20 studies (928 cases) were classed as 'high-tech' (although the author finds success drivers equally applicable in general projects). The Analytical Hierarchy Process (AHP) was then applied to reveal a ranked set of success drivers, followed by consistency tests to check fidelity. Several of the higher scoring factors are directly applicable at the planning, formation (FEL) and project approval stages. Table 1 shows the comparative ranking of selected general, and high-tech, project

success drivers shown to impact strongly on early project shaping.

The ranked project success drivers reveal valuable insights for improved front-end stage PM. Overall, a relatively small number of key project aspects are demonstrated to impact primarily on the chances of success. Most significantly, implementation of competent project control systems and processes, and a clearly defined project mission are shown to be twice as important as the next ranked driver (mature project information systems). These considerations are important throughout the project but it is clearly necessary to test the intent, strength, and understanding of the project objectives at the conceptual/approval stage. Second, the overall rankings show the importance of 'softer' indicators such as stakeholder engagement and expectations management, and instilling the right amount of urgency.

In the following sections, I expand on five topics that show positive correlation between the casework and the meta-data studies when examining the importance of shaping at mega-project front-end stages.

Figure 2. The continuum between control and chaos
Remington, 2011 p. 18.

Managing Complexity

The technical, logistical, and environmental hurdles that face complex mega-projects are daunting, even for seasoned practitioners. Complex systems theory describes degrees of complexity ranging from highly complicated to almost chaotic (see Figure 2). In such systems, it is not intuitively obvious how the impacts on a complex project may affect the outcomes.

System complexity tends to grow in response to ever more demanding science and technology applications, especially in relation to performance and reliability. For large high-tech projects that involve a site requirement (e.g. nuclear plants, particle colliders, etc.) institutional factors add further complexity, as well as stakeholder interests (Helmsman, 2009). The International Complex Project Management Task Force (ICCPM, 2011, p. 18) cites complexity as, “embodying uncertainty, ambiguity, dynamic interfaces and significant political or external influences. Such projects often [run] longer than the lifecycle of the technologies involved.”

The ‘players’ too shape the character and dimensions of the project. While the project office may hold the status of project integrator, the prime contractors too must be capable of complex PM. For cutting-edge programs, the system integration activities alone pose serious challenges in terms of industrial skills and capabilities. Much of this how-to knowledge is not codified, and casework

verifies that particular projects are much more than just complicated and difficult; they have special characteristics that pose extraordinary management challenges not always recognised at the outset by institutional agencies (ITER, 2009; ILC, 2009; ALMA, 2014; ASKAP, 2014; SKA, 2014).

Geraldi et al. (2011) assert that the use of tools for complexity analysis increases understanding of how to manage complexity at project start, e.g. helping to formulate the business case. The well-known Helmsman Complexity Scale (Helmsman, 2009) offers a useful comparator tool empirically derived from research across multiple industry sectors and underpinned by scientific and technical rigour. The scale clearly places global, high-tech mega-projects at the highest levels of complexity.

The International Centre for Complex Project Management (ICCPM) offers a more scientific Project Complexity Assessment (PCA) tool designed to create broad awareness at the early stages of projects of an organisation’s capacity to deliver; thus informing the likely success of the project. Then there are the mathematical models. Through his equations and extrapolations, Sessions (2009) shows an almost linear relationship of complexity to project early failure rates. Thomas and Mog (1997) investigate complexity as a function of the interactions between system components over time. Their approach informs technology readiness and programmatic risk, but is a non-trivial exercise in mathematics.

Table 3. Complexity elements in mega-projects

Technical	Organisational	Environmental
No. of goals	Project duration	No. of stakeholders
Clarity of goals	Size in capital expenditure	Stakeholder perspectives
Size of scope	Size in engineering hrs	Political influence
Uncertainties in scope	Size of project team	Internal support
Quality requirements	Size of site area	Required local content
No. of tasks	No. of locations	Interference
Variety of tasks	Resources, skills availability	Climate and weather
Dependencies between tasks	Experience in parties	Remoteness of site
Uncertainty in methods	Health, safety & environmental awareness	Experience in the country
Interrelations between technical processes	Compatibility between methods & tools	Dependencies on stakeholders
Conflicting Standards	Contract types	Strategic pressure
Innovation level	No. different nations	Project stability
Experience level	No. different languages	Level of competition
Technical risks	Cooperation JV partner	Environmental risks
Technical dependencies	Interfaces between disciplines	
	No. of financial resources	
	Trusted relationships	
	Organisational risks	

Adapted from Bosch-Rekvelde et al., (2010).

More palatable to PM practitioners, Bosch-Rekvelde, Jongkind, Mooi, Bakker, & Verbraeck, (2010) present a readily applied TOE (technical, organisational, environmental) framework to group (though not evaluate) the elements of project complexity, especially at the start-up phase (see Table. 3). Practitioners interviewed readily agreed that just having a shared understanding of the complexity dimensions within the project team aids comprehension and decision-making.

While the number and scale of complexity factors is shown to be an indicator of project execution difficulty, the fieldwork interviewees also mentioned the positive impacts of aspects of team diversity, spreading of risk, and varied sources of experience (ALMA, 2007, ATCA, 2009, XFEL, 2009, LOFAR, 2009). These findings accord well with an Australian study of defence projects (Helmsman, 2009). Although a basic knowledge of complexity theory is required of PMs, access to and implementation of practical tools and guides

to address complex project problems are also needed (Remington and Pollack, 2009)

Success Criteria and Setting the Project Goal(s)

Success criteria, comprising critical success factors (CSF), should not be confused with success *metrics* which can be set later. Success factors may be quantitative or qualitative, and expressed as goal statements, core and non-core benefits, and/or longer term objectives (SKA, 2014). Several casework projects placed user-community satisfaction far ahead of meeting budgetary or time constraints (ITER, 2009; LIDAR, 2009; XFEL, 2009; ASKAP, 2011).

Tolerance in meeting project success criteria will vary between projects. Stakeholders too, have different views of success, and diverse positions in terms of interest, influence, attitude, and requirements (British Computer Society, 2006).

Each project's set of performance measures is thus unique, and cannot be considered in a generic sense, even when a new project is modeled on a proven design (SYNCH, 2009).

In seeking to formulate a new approach to successful project execution, Shenhar and Dvir (2007) argue for a holistic technique when setting success criteria. Their model involves at least five fundamental dimensions (or 'soft metrics'):

- Project efficiency,
- **Impact on the Customer:** Meeting requirements and achieving customer satisfaction, benefits, and loyalty,
- **Impact on the Team:** Satisfaction, retention, and personal growth,
- **Business Results:** Return on investment, market share, and growth,
- **Preparation for the Future:** New technologies, new markets, and new capabilities.

The casework found that a considerable benefit of early declaration of success criteria is their use in front-end phases where project re-shaping, or even termination, is cheapest (Cooper, 2006).

Procurement (Contracting) Processes

Whatever the final cost reality, all complex engineering mega-projects commence life with a forecast budget, often into the billions of dollars. Such investment levels create expectations of financial competence including professional management of procurement. Despite this, the acquisition of goods and services for projects has traditionally been seen as largely administrative or operational rather than having strategic importance (Jaakkola, 2004; Crosby, 2011). However aspects other than purely transactional show a maturing of approach to procurement echoed in several of

Table 4. Nine procurement success topics and their associated Key Success Actions

Topic	Key Success Action
The procurement office/function	No later than the pre-contractual phase, establish the procurement office structure, resources, roles and responsibilities, and information management systems.
Procurement strategy, policy and planning	Formally approve procurement principles /strategies, policies, and plans, and document these within a concise approved and controlled Project Procurement Plan.
Informed contracting with industry	Obtain full understanding of global capability 'scouting' information, and employ appropriate approaches and procurement instruments with terms and conditions supporting project success measures.
Contracting models	Establish the permitted contracting model(s), aligned with the legal entity. Develop relationships with principal contractors and key components of the supply chain.
Ensuring competitiveness	Ensure competitiveness in contracting, through carefully planned pricing strategies, and a broad 'value for money' approach.
Procurement specifications	Apply purchasing specifications that are appropriate to the goods or services required, flexible for optimal outcomes, and developed with input from industry.
Procurement risk	Understand and actively manage industrial relationships and procurement risk, including the critical early stage engagement phases. Site readiness plans should include industry capacity and capability confirmations.
Tender evaluations and contractor selection	Evaluate and select project contractors using a fair and defensible process, and focussed on criteria weighted in favour of supplier reputation and investment, and mission success parameters.
The purchaser-supplier relationship	Implement fair and transparent procurement processes, and where obviously desirable, exploit ongoing strategic partnerships. Allow for evidence-based supplier compliance and quality inspections.

Crosby, 2011.

the case studies (ALMA, 2008; LOFAR, 2009; LHC, 2009; OPAL, 2009).

Rendleman and Faulconer (2011) demonstrate the importance of closing the gaps between available technologies and customer needs before beginning an acquisition so as to shape programs for success. Schill (1979) points out the strategic liaison role played by procurement to ensure that suppliers remain competitive and at the forefront of technology, as well as realise better cost and product performance. Moreover, he assigns strategic responsibility for materials and technology identification – a key tactic identified in the procurement scouting activity developed for the SKA telescope project (Crosby, 2010).

Investigations into effective mega-science project procurement (Crosby, 2011) reveal nine specific topics of attention. These are listed with associated Key Success Actions in Table 4.

A common theme among the Key Success Action is relationships, with the strong implication that traditional open tender procurement methods (EoI, RFTs, RFQ, etc.) are not always the best basis for effective acquisition in complex mega-projects. While not proposing a wholesale shift from ‘quote-supply’ processes, the often taxing experiences from the case studies (ALMA, 2009; ITER, 2009; LHC, 2009; ASKAP, 2012;) uphold the potential overall advantages of alliance-style contracting in the form of cooperative relationships.

A strategic partnership is much more than a motherhood catchphrase, and is fundamentally about trust; based on competence, interdependence, and integrity. This means cooperative and transparent relationships with shared risk/reward, and in their highest form, without competitive bidding in the traditional sense. Although more cautious, Merrow’s (2011) deep study of industrial megaprojects also supports alliances as viable industry participation models, while emphasising that each mega-project must decide its own most suitable procurement approach. Merrow’s findings concur with the author’s casework in that around half of all contracting was of the institutionally mandated ‘lump-sum’ type, even though such

arrangements tended to be less cost-effective and rarely reflected the final price paid.

Resilience-Building

Continued high-tech project failure has directed renewed investigations into early factors that help drive project resilience and robustness. Crosby (2012a) for example, identifies nine key early prerequisites for complex mega-project resilience. These are grouped into two types:

- **Attitudinal:** (Realism, fact based, a lessons-learned culture, ambiguity/uncertainty tolerant); and
- **Conditional:** (A defined mission, clear reporting and decision structures, strong information control, preparedness for unknown risk, external environmental awareness, and mission assurance).

Of these, three factors considered central to the project shaping process:

1. Project Realism

Large complex projects are naturally instigated in the enthusiastic belief by the protagonist(s) that they can be executed on time and on budget, and achieve their promised outcomes. Too often this optimism bias leads to underestimation of the difficulties (Grün, 2004). A UK Government Guide (UK Treasury, 2003 p. 86) specifically links the cause of over-optimism in project costs to, “poor definition of the scope and objectives of projects... due to poor identification of stakeholder requirements, resulting in the omission of costs during project costing”.

Evidence of the optimism ‘curse’ is not hard to find. A radio astronomy White Paper (Fisher, 2010) describes overly optimistic cost and time estimates as the most frequent cause of project de-scoping. A UK defence report (MoD, 2009 p. 5) lamenting a £205 million cost increase over 20 projects admitted that, “on far too many proj-

ects, the Department is over-optimistic and sets unachievable cost, time and performance objectives”. Butts and Linton (2009) who investigated NASA’s cost estimation performance, conclude that undershooting cost and schedule projections is common practice, borne out by NASA Director, George Morrow’s warning (NASA, 2009 p. 31) that, “a major pitfall is being overly optimistic early in the project lifecycle”. Over-optimistic budget and schedule expectations inhibit project success, and are especially likely on projects with institutional difficulties. IT projects also appear to be especially vulnerable (Verner and Cerpa, 2005; Mieritz, 2012); Flyvbjerg & Budzier, 2014).

Optimism phenomena were observed in the casework, most obvious within ASKAP, ITER, and the SKA. In each instance both schedule and cost were (and continue to be) stretched as the challenge of settling the design and transitioning through construction phases tests each deadline, prompts revised baselines, and raises fresh funding questions. Concerns over realism in estimates were rarely conveyed above PM level in organisations.

How then might we recalibrate our thinking? Blanchard (1990) claims objectivity may be the only defence and suggests that, as a balancing process, project proponents should also develop a case for *not* proceeding. Flyvbjerg et al. (2003) argue strongly for bona-fide cost estimates accompanied by risk analyses of future cost regimes. Flyvbjerg (2013) strongly promotes taking an ‘outside view’ through the Reference Class Forecasting technique. Further advice for dealing with over-optimism in complex projects is contained in a brief, but pithy, guide from the UK National Audit Office (NAO, 2013).

2. Lessons Learned

The benefit of advice from like-projects seems axiomatic, yet research for this chapter found little evidence of planned effort for this. None of the case study projects budgeted for even perfunctory enquiries of similar projects. Learning from one project to the next is strongly advocated in the

practice literature, though academic studies find that few organisations manage this systematically to any depth, or in a useful format (Verner and Evancho, 2005; Atkinson, Crawford, and Ward, 2006). Smith and Winter (2010) directly link competent front-end management with project success while promoting the idea of deliberately exploring insights and implications flowing from past projects.

When pressed by the author, interviewees agreed that simply assuming that lessons from previous projects have tacitly informed future projects is insufficient. Organisations must take steps to accumulate and disseminate the learning before it dissipates. In other words, knowledge gained ‘ad-hoc’ will not naturally lead to retention of project insights; a shortcoming dubbed as ‘project amnesia’.

Case research found that the majority of organisations that do undertake a lessons-learned activity do so through meetings or workshops - activities that Williams (2008) shows to be well correlated with increased perceptions of success and markedly increased PM competency. Examples in successful project organisations show that the ‘fault-line’ of failed knowledge transference can be effectively bridged by ‘communities of practice’ as stimulants to successful cross-project learning (Fig. 3)

Innovative organisations are more likely to use corporate training, searchable databases, and transfer lessons-learned into organisational procedures. Often missing (yet easily implemented) is a policy requirement to revisit lessons from previous projects as a prelude to new project planning.

3. Mission-Assurance

One phenomena of complex project execution that surfaced sporadically among the case studies (ALMA, 2009; SYNCH, 2009) yet is more overt within industry and aerospace organisations was that of mission-assurance. In essence, it translates to an unwavering sense of purpose in making mission success the highest priority at all

Figure 3. Showing how communities of practice bridge the project knowledge fault-line

levels of the project. The adoption of a mission-assurance mindset is revealed most compellingly within NASA where the post-2001 integration of a formal Mission and Safety Assurance function correlated to a lift in mission success rate from 90% to almost 95% (Crosby, 2015).

The author's research supports the appointment a dedicated Mission Assurance person or group at the project concept stage. This function (part auditor, part advisor, part 'devil's advocate') should be positioned outside of mainstream project delivery, yet close enough to have ready participation in critical testing, meetings, and reviews, and with access to top level project management. This crucial role is not about meddling or being an undercover agent, but principally one of questioning and checking that activities, deviations and changes pose no unrecoverable threat to project execution and performance.

Beyond Traditional Risk Management

Conventional (PMBOK style) risk matrices used to self-score risk intensity by rating likelihood and consequences are common PM artefacts and were observed in all the case studies. Such tools appear to at least identify a view of known risk exposures at project start. However review and/or update of resulting risk registers as the project unfolds, or the systematic application of mitigating controls, was rare. But perhaps this lack of appli-

cation matters little, since a growing number of researchers consider that such arbitrarily chosen risk ratings are mostly worthless, due largely to the effects of cognitive bias and human variance. In their study of IT project success, de Bakker, Boonstra, & Wortmann, (2010 p. 499) conclude, "risks for which there is no classical or statistical probability distribution cannot be managed by means of the [rational] risk management process".

The inability or reluctance to plan for non-rational, unexpected massive negative (or even positive) impacts is investigated deeply by Taleb (2010) who classifies such events as 'Black Swans'. Taleb forcefully argues that the tendency for humans to scale and smooth predictions on assumed or unfounded (i.e. guessed) data guarantees erroneous forecasts. The author's observations within the high-tech mega-project environment confirm these tendencies, with highly rational scientist and engineers lacking skill when dealing with complex programmatic and social matters. Green (2012) adds the crucial point that project planners should not be fooled by the statistically insignificant frequency of Black Swans, but should instead pay close attention to the potential catastrophic consequences.

Geraldi et al. (2010) support observed data that unexpected events will inevitably emerge in large complex projects; likely surfacing from the external project environment, e.g. political turmoil, supply chain failure, exchange rate fluctuations, or even weather events. Miller and Lessard (2000)

report an average of five unexpected events in the formative stages of projects, with some confronting as many as 12. Two of the case studies (ALMA telescope, Australia Synchrotron) experienced such misfortunes.

How might complex projects be better shaped in terms of risk? First, it is prudent to invest in preparedness not prediction. Green (2012) promotes ‘uncertainty spotting’ skills sensitive to the early weak signals of threats and assumptions through active awareness – especially geopolitical and economic developments. In their study of tools for complex projects, Remington and Pollack (2008) discuss non-linear risk events requiring early decision-making so that even if managers cannot directly predict the source or possible ramifications, an ‘atmosphere of preparedness develops’.

FUTURE RESEARCH DIRECTIONS

Future research could usefully further investigate reasons for project success. Whereas there are clearly many single-point causes for failure, project triumph can only occur when all barriers are surmounted, and the project not only meets its programmatic goals, but also satisfies its customers and critics. It is project success, not failure, which offers data richness.

The author’s research suggests that the world of military contracting holds further learning in the area of mega-science project management, especially programs that integrate, and continually upgrade technologies. Future research in this genre should derive useful lessons regarding through-life project support, and joint agency execution of high-reliability programs.

Lastly, while a large amount of ‘know-how’ around PM is codified in guidebooks and articles, theory development and discussion tends to reside in academic circles, such as in Operations Research (e.g. Gerald, Maylor, & Williams, 2011). This means that epistemic insight into mega-project delivery often remains unseen by

working project managers. Inclusion of this chapter in the Encyclopedia of Information Science and Technology represents a proactive move by the publisher (IGI Global) to bring new and useful wisdom to project practitioners– something that can only be encouraged.

CONCLUSION

This chapter described the potential for specific, and often less obvious, factors that influence success in large and complex engineering/science projects (though probably equally effective in general mega-projects). Five topic areas were developed as being especially important at the front-end stages, leading to the following conclusions:

- Traditional PM skills and techniques are insufficient to properly plan or manage the complex dimensions of high-technology mega-projects. However wisdom exists to master and shape complex projects if we seek it.
- A detailed goal set (or mission) must be clearly articulated, including hard and soft definitions of success.
- Large high-tech projects are more than just complicated and difficult. An assessment of project complexity is essential in order to effectively plan for resources, cost, and risk.
- Procurement is strategically important to success, and not merely an administration function.
- Building project resilience requires curbing optimism, formally researching lessons-learned and implementing a mission-assurance function early.
- Project meta-risk and preparedness for the unknown is required. This includes identifying boundary threats at project outset, and shielding from the consequences of ‘Black Swans’.

- New findings from this research strongly argue that it is not enough just to attend to each of the factors described above, but rather they all need to be tackled together for synergistic results.

KEY TERMS AND DEFINITIONS

Black Swan: An event that comes as a surprise, has a major effect, and is often inappropriately rationalised with the benefit of hindsight.

Books of Knowledge: Standards for project management most commonly issued by professional Institutes. They contain the basic processes that project management experts agree are necessary for most projects in most environments.

Communities of Practice: A group of people who share a craft and/or a profession and created specifically with the goal of gaining and sharing knowledge related to their field.

Optimism Bias: Manifests itself in projects as an underestimation of the time, costs and risks to delivery and the overestimation of the benefits.

Procurement: Procurement is the acquisition of goods, services or works from an external source. It should include activities ranging from market scouting through to post-contract reviews.

Project Lifecycle: Refers to a series of activities which are necessary to fulfill project goals or objective, including; planning and concept design, commencement, execution and review, final review and learning.

Resilience: The ability of a project to readily resume from unexpected events, threats or actions.

Staying Ahead in Business Through Innovation

M

N. Raghavendra Rao

FINAIT Consultancy Services, India

INTRODUCTION

Many business enterprises rush into generating ideas to become more innovative before clearly identifying the problem in their enterprise. If the enterprises expect their employees to come up with ideas that would work, the employees need to know the business problems faced by their organization. The employees must have access to the information pertaining to the problems of their organization. It is the practice of many enterprises that their organization's information is considered as important and is also kept as secret. It is meant for the management's view only. The environment in enterprises must be friendly instead of closed. Then only the employees will associate themselves with their organization. This would facilitate them to integrate creativity and strategic thinking. Creativity is certainly a part of innovation but innovation is much more (Tocci, Chesbrough, & Piller, 2016).

It is observed executives in enterprises are under the impression that innovation is associated with new products, new technology, and research development activity. This view is too narrow in the presence of business scenario. Innovation can be applied broadly across all aspects of an enterprise. They are such as existing products, services, business processes and business models.

Peter Drucker in his article on the discipline of innovation says that innovation is real work. It should be managed like any other corporate function. Further he explains that it does not mean the same as other business activities. He stresses that innovation is the work of knowing rather than doing. He argues innovative business

ideas come from methodically analyzing seven areas of opportunity. The areas are 1) Unexpected occurrences 2) In Congruities 3) Process Needs 4) Industry and Market Changes 5) Demographic Changes 6) Changes in Perception and 7) New knowledge. He groups the above areas of opportunity are under within a company or industry and outside a company in its social and intellectual environment. The first four areas fall under the group one and the balance three fall under group two. The glass is half full and the glass is half empty are the descriptions of some phenomena, but have vastly different meanings. Changing a manager's perception of a glass is from half full to half empty opens up big innovative opportunities.

BACKGROUND

Globalization has created new trends such as market consolidation, Vertical Market strategies and mergers in the business world. These trends have forced many business enterprises to adapt themselves to these new phenomena (Estrim, 2009). Now it has become a necessity for many business enterprises to look for "New Approach" which can help them to face new realities in business. The most talked about and discussed about the "New Approach" in the business world is "Innovation Management.

History of Innovation

Innovation has always been part of mankind. Since the discovery of fire by rubbing two stones together, human beings have been innovating.

DOI: 10.4018/978-1-5225-2255-3.ch495

Innovation is probably the oldest known process. In other words innovation is an extension of a person's creativity. Human beings have been using their inner skills to create many new things to help mankind.

Historical Background of Knowledge Management

The concept of knowledge management is not new. The focus and approach has been changing over a period of time. One may observe from the literature on the history of information and knowledge that the basic patterns of behavior remained constant over a period of centuries concerning the role of information and knowledge. History provides many examples. Emperors in the olden days always surrounded themselves with advisors who were scholars first and politicians second. Roman emperors like the ancient Greeks consulted educated priests to gain an insight into the possible future. Indian Kings seemed to be concerned with creation of knowledge among people by allocating places for schools and libraries. Julius Caesar used innovative construction methods and advancements in armaments to achieve military success. Napoleon made use of the advancements in artillery to defeat his opponents. Cornelius Vanderbilt had taken advantage of the advancements in rail road wheels and brakes to create vast commercial empire. J.P.Morgan made a huge fortune and revolutionized the financial system by developing modern investment banking practices. Tipu Sultan used war rocket in some of the battles he fought against the British soldiers. This earned universal fame as "Innovator of the World's first war Rocket". It was his victories against the British forces that ranked Tipu Sultan among the few Indian rulers who have defeated the British.

In the pre industrial era agriculture was the basis of nation's economy then the concentration was to learn more about farming. In the post industrial era manufacturing became the basis of nation's economy then the concentration was to

learn more about manufacturing techniques. In the present globalization scenario the focus is towards adapting innovation and process speed in business enterprises. Knowledge base in a business enterprise is an extension of knowledge sharing systems. Business success lies in converting the information into knowledge. In today's business scenario the use of sophisticated knowledge base depends on the skill with which executives in business enterprises arrive at their findings from their analysis for framing strategy for their organization. Further business executives can draw insights from the large information stored in their systems. Conclusions drawn from these analyses will help the business executives to involve in innovation.

Indian and Chinese Thinking

Jugard is a colloquial Hindi word that roughly translates as "Innovative Fix" (Radjou, Prabhu & Ahuja, 2012). It is an improvised solution born from ingenuity and cleverness. Jugard is quite simple. It is a unique way of thinking and acting in response to challenges. It is the gutsy art of spotting opportunities in the most adverse circumstances. Further it is making use of available resources fully improvising solutions by simple means.

Juggard is practiced by almost all Indians in their daily lives to make the most of what they have. Juggard applications include finding new uses for everyday objects such as empty soft drink or pickle bottles reused as containers for water, spices or lentils. When a truck cannot be repaired, diesel engine is removed and used as a cart. Juggard happens in an emergency situation. It is not a planned activity. Chinese believe in today's world the primary resource is knowledge and innovation. This resource comes from one's brain. If one's brain retires, then there is no more life (Sunted, 2011). The level of innovative thought will be one of the major economic drivers for China. Many global organizations have already established offices in China to capture both the creative kinds of its people and the tremendous market share.

TRENDS IN MANAGEMENT CONCEPTS

One can find from the analysis of trends in management in every decade. New concepts have been emerging. The moment it emerges, it is considered as “Next Big Thing” or “Next Important Concept”. In 1950’s “Brain Storming” Concept has become popular. It was considered to be a very important factor in involving the employees in business enterprises to generate new ideas. In 1960’s and 1970’s, sensitivity groups have played an important role in business enterprises. The group leaders of this group have been considered to be “Gurus”. They have been to lead group managers. Then it has been practice, “Gurus” would make brief opening remarks and they would wait for response from the group managers. Then the “Gurus” would facilitate them to express and try to clarify. It was a hope that “Inner Manager” would emerge. It was expected that more research would follow on their deliberations. The era 80’s was considered as the age of quality management. During this period quality control, quality circles, six sigma and other related approaches were followed for enhancing workers performance. The quality related approaches have been continuing for a long time. In the recent past, the need for knowledge management has been felt very much to globalization. In the present era the concept of “Innovation” is becoming ultimate goal of enterprises to face the complex global economy (Vint, 2009).

Invention, Innovation, and Creativity

The terms invention and innovation are used interchangeably. Actually these are separate and distinct concepts. Invention means designing and creating something which has never been made before. The classic examples are invention of light bulb by Thomas Edison, and Invention of telephones by Alexander Graham Bell. Louis Pasteur came up with vaccines. Innovation deals

with bringing in new methods and ideas resulting in required changes in an enterprise. In the present business context, innovation is taking interesting ideas and transforming them into usable solutions (Vangundy, 2008).

Creativity can be defined as discovery of a new idea or connection. Many ideas already exist somewhere in the World. Creativity is to identify these ideas and connect them in a new way. But innovation is much more than just identifying and connecting these creative ideas. It is about strategy and action bringing values to the enterprise through the implementation of these creative and strategic ideas. Innovation can therefore be interpreted as the profitable implementation of strategic creativity.

Example for Invention and Innovation

John Shepherd Barron reached his bank a little late and thought that why there could not be a system to get cash on the lines of chocolate vending machine. This thought gave him an idea to invent the first automatic cash dispensing machine now known as ATM. John had also thought of the four digits PIN Number. Creation of ATM can be considered as a classic example for invention and innovation. Many more features are being added to ATM by other people. Invention of ATM has given a scope for adding additional features in ATM. The enhancement of additional features can be considered as innovation.

Types of Innovation

Innovation can be applied broadly across all aspects of an enterprise such as existing product, services, processes and business models (Prahalad & Masshelkar, 2011). Innovation can be classified under three categories. They are 1) Efficiency Innovation 2) Evolutionary Innovation and 3) Revolutionary Innovation.

Efficiency Innovation

Efficiency Innovation talks about the changes in the existing processes in enterprises. The management is generally happy for small changes made in the existing processes and procedures in their organization. This approach is usually to cut costs, reduce cycle time or designing a simple format of a report to the top management of an enterprise.

Evolutionary Innovation

Evolutionary Innovation concentrates on ideas that represent something distinctly new and better. An example under this category is the introduction of internet banking. This has changed banking business from the fixed hours to banking at any hour. The other example under this type is advertisement in tabloids. Advertisements make the publishers of tabloids possible to distribute news free of charge with the revenue from the advertisements. The business models such as B2C, B2B, and B2G have been providing a scope to innovate improvements and expansion in enterprises.

Revolutionary Innovation

Revolutionary Innovation focuses on something radically new. This may change the existing structure of an enterprise and market place. McDonalds approach to fast foods changed the restaurant business. Disney's unique characters and interactive theme parks changed the entertainment business. Internet has brought a change in business scenario. It will continue to change in the industry sectors also.

Need for Innovation

The innovative spirit among the inventors is responsible for inventing the car, the telephone, television, and the internet. The world is benefited from manifestations of the innovative spirit. One may wonder what makes the need for innovation

different in the present day context (Chesbrough, 2011). Business World is in the middle of significant transition. Three factors are playing important role in the present transition period. The three factors are information technology, the expanding world, and demanding customers.

Need for Clear Focus

The important aspect that is required in an enterprise is the type of innovation it wants to pursue (Dastur, Sawant, & Bawa, 2012). There will be conflicting views among the executives in enterprises. Many times ideas suggested by the employees are not encouraged for fear of the unknown once they are presented. Enterprises generally support very small impact of efficiency innovation. It is very important at the beginning of any project to discuss the type of innovation the enterprise is expecting. Decision has to be taken in light of the available resources such as the core competencies and culture of the enterprise. Innovation momentum for an enterprise is like a snow ball. Snow ball gains in size and power as it rolls down the hills. Similarly an enterprise gains power as more and more employees adopt an innovative attitude and succeed in finding distinctly new and better ideas.

Enterprises cannot afford to depend on one person or one department to focus on the future. They need to have every employee in every area of an enterprise to be on the lookout of innovative ideas. It is the tendency of the employees to continue old and comfortable way of doing things. Sometimes it is a tough proposition for the employees to drop their emotional attachment to the way they are presently working. Enterprises need an innovation road map and detailed action plans. Innovation road map is required to enable enterprises in the creation of innovation centric organization. Innovation road map should address knowledge and skills of employees for innovation environment of an enterprise (Dyer, Halgregeresen, & Christensen, 2011).

Knowledge Harvesting

Knowledge harvesting is an integrated set of processes that allow the often hidden insight of human expertise in business enterprises to be captured. Then it is converted into a specific actionable know-how that can be transferred to others. The actionable know-how will be stored in an information system which will help thereby to create organizational value and enhance in decision making processes, record facts about critical decisions. Further it will facilitate to create Meta knowledge about actual working adapted to changes (Lester & Piore, 2010).

The word “Harvesting” generally applies to agriculture. It refers to the practice of increasing the yield of cultivable land. In the same way organizational databases are considered as equivalent to cultivable land. In the context of organizational environment, the employees “Wisdom” can be considered as “Manure”. The employees wisdom will help the data in the system to be converted into useable information.

Case Illustration

3G textile mill is one of the leading textile mills in India. This textile mill has been in the business over five decades. The unique aspect of this mill is that is being managed by a management consisting of president, senior president, and vice president who belong to three different generations. Their approach and decisions are based on their experiences, business insight and education. All the three in the top management team keep updating themselves new technologies in their textile business besides keeping them aware of new trends in information technology and market trends. They are assisted by a team of executives who have rich experience in the respective field of textile industry.

3G textile mill has been manufacturing cloth material for western and eastern ladies requirements. They also manufacture shirting, and suiting materials besides producing readymade garments

for men and women. They enjoyed major global market share for their products till the globalization policy followed by many countries. It is because of changing scenario in the global market, their market share is affected. Consequently their profits have been fluctuating. The top management along with their team of executives have analyzed that they have cost advantage over their competitors. They have edge over in the process technology and size of business enterprise. They have come to the conclusion, after the analysis is that their weak link is in the fashion technology. They hired the services of domain experts in the field of textiles who are familiar with the tastes of people in European countries and Eastern countries. They expected that their guidance will help them to improve their global market share. The domain experts have their offices in Paris and Singapore.

Cloth Material

Cloth material is designed by the domain experts from their experience based on the needs of the consumer requirements such as color combination of dyes with the cotton mix. The domain experts have made use of the virtual reality concept in designing the cloth material according to the latest trends in the European and Eastern countries.

Readymade Garments

The domain experts have taken into consideration the latest trends in the fashion in the European and Eastern Countries. The domain experts designed and created garments on the basis of real world requirements of the two countries (Gallo, 2012). Simulated versions of readymade garments are carried out in the computer systems under the cloud computing environment. The concept of virtual reality helped them to look from the real world situation. Resources in cloud computing environment have made it possible for the domain experts to create designs for the requirements of 3G textile mill.

Management Team of 3G Textile Mill

The management team along with their technical executives in India is able to view the design of cloth material and design of readymade garments on their system. They have suggested the changes wherever they felt they are required.

Social Media and 3G Textile Mill

The management team at 3G Textile Mill has realized that the market place is about brands and consumers speaking to each other. Further brands have been losing control over the kind of conversation that is taking place about the brand. The internet has moved the control of brands into consumers' hands and that is posing new challenges for brand owners. It has become a necessity for brand owners either need to have more people speaking positively about the brands or have fewer people speaking negatively. Social media plays a crucial role in both the cases. They have realized the need for exclusive social media sites for business activities.

Marketing Wing

The management team has felt that the concept of social media is to be made use of for their business. A sample cloth material and garments have been designed by the domain experts with their experience, knowledge and also with the inputs from the executives of the 3G Textiles. The concepts of virtual reality and multimedia are applied in creating a material with the different combination of colors. While designing the cloth material, the types of dyes available in the market are also kept in mind.

The marketing department of the mills has created an exclusive social media channel for the prospective customers to express their opinions of the proposed design of a cloth material and garments. The proposed design of their products is uploaded in the site. Vendors of dyes have been

informed to visit the social media site to get an idea the types of dyes are to be supplied once the proposed design is finalized.

Interactions with the prospective customers on the social media site have facilitated them to understand their needs and tastes. This has helped the mills to design a cloth material and garments from the data and information from the social media site created exclusively by the marketing department (Chang & Taylor, 2016).

This Case Illustration gives an overview of the approach followed by the textile mill to design a cloth material for ladies making use of the concepts such as virtual reality and multimedia. The feedback from the prospective customers on the social media channel facilitated them to finalize the design of the cloth for production. Further vendors who supply dyes and raw cotton are able to get the required information for supplying the materials as per the requirements of a new design. Customers' tastes are becoming more homogeneous around the globe. The feedback on social media channel facilitates to innovative approach (Chiporni, Chiesa, & Frattini, 2011).

Innovative Approach

It is clear from 3G textile mill's innovative approach that new products can be designed and developed by the domain experts who are away from the Indian soil. This is because the domain experts' involvement of the process of continuous exchange of ideas among the members of virtual team dispersed across the globe. This process helps in generating alternative ideas by taking inputs from different sources and structuring through virtual reality applications. This model provides an idea for the creation of global innovative approach. It facilitates to structure the work flow by visualizing the various phases of the development of a product.

In today's knowledge rich environment, 3G textile mill has proved that enterprises can no longer afford to rely entirely on their ideas to

advance their business. It may be noted that they have not restricted their innovative approach to a single path market. As a result the traditional model of innovation which has been largely internally focused or a “Closed One” has become obsolete. Emerging in its place is a new paradigm “open Innovation”. This strategically leverages internal and external sources of ideas and takes them to market through multiple paths. Global enterprises can take advantage of unique knowledge and resources wherever they are located. Information and communication technology has created virtualization in activities and ways of working. The approach of 3G textile mill explains in adopting innovative approach. Further it applies the concept of “Mind Invoking” (Govindarajan, & Christrimble, 2011).

Approach in Case Illustration

3G textiles felt for the need for innovation. They have a clear focus in their innovative approach. They have applied revolutionary innovation method in designing and developing a product. They have involved their executives along with the domain experts in the innovative approach followed by them. They have made use of the concepts such as virtual reality, cloud computing and knowledge harvesting in their product designs. It is interesting to note that the management team consists of three different generation people. They are ready to adopt innovative approach to face the challenges in the present globalization scenario. It is apt to note the observations of Linda A H, Greg B, Emily T, & Kent L, (2014) in their book that though each of our leaders and their firms differed in key ways all leaders paid particular attention to making sure their organizations were able to collaborate, engage in discovery driven learning, and make integrative decisions. In the case of 3G Textiles the top management team, executives in their organizations, domain experts, vendors, and the prospective customers worked as

a team to apply revolutionary innovation approach (Gupta, 2009).

Future Trends

The future of innovation is bright. It may be said there is no future without innovation. Adopting new methods and designing of products will ultimately be overtaken by new innovative approach. Innovation is the topic for twenty first century business. It is considered to be a primary source of competitive differentiation. Further it will be the most important driver of growth at corporate level and even at country level.

CONCLUSION

The unique approach to innovative thinking involves the integration of creative thinking, strategic thinking and transformational thinking. The role of innovation in any economy is to be addressed to knowledge performance, skills, innovation environment, and progressive thinking of communities. It is apt to recall Peter Drucker's observation on seven basic sources of innovation. They are 1) The surprise of unexpected success or failures, 2) Inconsistencies when things do not add up according to conventional wisdom, 3) Desperation when there is a crying need for a better way, 4) Outdated industries or processes over due for change, 5) Life styles or demographic changes, 6) Attitude changes of customers, and 7) Discovery where new knowledge or capabilities promote new opportunities. The industry landscape is changing because of the content in social media sites. This will be helpful for enterprises to plan their business activities. It is not about east or west or developed markets versus developing markets. We have become more of a connected world. Ideas can come from anywhere.

KEY TERMS AND DEFINITIONS

Cloud Computing: A Computing Model that makes information technology resources such as servers, Middleware, and applications available over the Internet as services to business Organizations in a self service manager.

Collaborative Technology: Various concepts in information and communication technology facilitate to work jointly in developing application software.

Core Team: A team consisting of domain experts to perform multi-Disciplinary activities.

Globalization: The process by which business starts operating on a global scale.

Knowledge Harvesting: Integrated set of processes that allow the often hidden insight of human expertise to be captured. Then it is converted into a specific actionable know-how that can be transferred to others.

Social Media: Use web technology to quickly disseminate knowledge and information to huge number of users. Face book, Twitter, Blog, and other similar social networking site are collectively referred to social media.

Virtual Reality: A system in which images that look like real three dimensional objects are created by a computer system.

M

Sustainable Competitive Advantage With the Balanced Scorecard Approach

Jorge Gomes

ISEG, Universidade de Lisboa, Portugal

Mário José Batista Romão

ISEG, Universidade de Lisboa, Portugal

INTRODUCTION

Why are some firms more successful than others? This question has been intensely debated by strategic management researchers over the last thirty years. Competitive advantage is recognised as being the major cause for explaining top organizational performance and is a fundamental goal of academic strategic management studies. Recently, there has been an increasing amount of empirical research on the subject of competitive advantage (Ray et al., 2004; Newbert, 2008) and about distinguishing competitive advantage from organisational performance (Powell, 2001). The relevance of competitive advantage is not simply determined by external factors, but also by those internal sources that have been considered critical for successful organisations. Porter (1985) says that competitive advantage is at the heart of organisational performance in the competitive business environment, and that the core of this view is that in order to achieve competitive advantage, firms should systematically provide added value to customers relative to the competition. Peteraf (1993) defined competitive advantage as being sustained performance above normal returns, and Barney (2002) claims that superior performance is obtained through the value generation of internal resources usage. The research of Wernerfelt (1984), Rumelt (1984), Barney (1986), Dierickx and Cool (1989), Amit and Schoemaker (1993) and Peteraf (1993) have all been recognised as a reference for the study of sustainable competitive

advantage (SCA), based on the resource-based view of the firm approach (RBV). According to this view, a firm's endowment of resources is that which gives it a sustainable competitive advantage. RBV highlighted the relevance of intangible resources as a crucial factor for SCA. Intangible assets, such as intellectual property, knowledge and skills of employees or relationships with our customers, are all sources of competitive advantages and long-term financial success, which are both increasingly important for organisations today (Kaplan & Norton, 1992, 1996, 2000). The competitive market environment and dealing with intangible assets have both become the main reason for SCA today for organisations, and they are needed to support organisations' strategy in reliable frameworks that measure strategy implementation, align business challenges with different internal activities, and include the management of IS/IT strategy, as well as other initiatives. The most globally-recognised management support system for fulfilling these organisational performance challenges is the Balanced Scorecard (BSC).

BACKGROUND

Sustainable Competitive Advantage

SCA is an organisation's ability to carry out the set of necessary steps for achieving lower costs than the competition in an efficient and unique way, creating differentiated value for buyers

Figure 1. How resources and capabilities combine to create differentiation

(Porter, 1985). SCA is the aim of every organisational strategy and it can be achieved in numerous ways. The rationale behind Porter's view (Porter, 1985) is that a higher performance is correlated with competitive advantage, and that achieving an advantage will certainly result in superior performance (Reed & DeFillipi, 1990). According to this approach, the organisational strategy definition depends on the external environment context. With the advent of the RBV approach, researchers focus mainly on the internal capabilities of the organisation, considering the external factors as background (Pralahad & Hamel, 1990; Spanos & Lioukas, 2001). The ultimate organisational goal is to achieve a superior return on capital through the identification, development, protection and allocation of resources and capabilities, and thus supply the organisation with a SCA (Amit & Schoemaker, 1993). RBV focusses on the development of resources and capabilities, supported by the belief that the set of resources in companies are heterogeneous, valuable and scarce (Collis & Montgomery, 1995; Hamel, 1994; Prahalad & Hamel, 1990), which are recognised as being a source of SCA (Barney, 1991; Barney & Wright, 1998; Wright, McMahan, & McWilliams, 1994). This approach assumes that firms can only create a SCA if they have superior resources, in conjunction with organisational capabilities, and that this combination is the best entry barrier for competition (Barney, 1991) (Figure 1).

Barney (1991) claims that for creating differentiating advantage, firm's resources and capabilities

must be valuable, rare, imperfectly imitable, and non-substitutable (VRIN). Intangible resources are the main drivers of performance sustainability across firms, and are usually tacit, difficult to codify (Kogut & Zander, 1992; Conner & Prahalad, 1996), and hard to acquire or develop, replicate, accumulate (Itami, 1987; Winter, 1987), and to be imitated by others (Rumelt, 1986; Dierickx & Cool, 1989; Nelson, 1991). It is this difficulty of imitation which makes them valuable and a SCA for a company (Lippman & Rumelt, 1982; Hall, 1993). Although subject to some criticism, some RBV authors (Peteraf & Barney, 2003; Amit & Schoemaker, 1993; Mahoney & Pandian, 1992; Conner, 1991; Barney, 1991; Wernerfelt, 1984) recognise the existence of bridges between both approaches and their complementarity in explaining the sources of firm performance (Foss, 1996). Teece, Pisano, and Shuen (1997), however, hold the opinion that an organisation has to establish dynamic capabilities to ensure its SCA. The dynamic capabilities view (DCV), which is supported by the RBV approach, notes that the dynamic capabilities of an organisation need to transform their resources into competitive advantages in order to generate competitive advantage. DCV emphasises the organisations' adaptability to the environment and their capability of creating and absorbing new knowledge, which is one important basis of its dynamic capabilities (Zollo & Winter, 2002).

According to the knowledge-based view (KBV), knowledge seems to be the most critical input and value source for a firms' process activi-

ties (Grant, 1996a), as all inputs are established on the foundation of knowledge. Knowledge is the most important resource that a firm possesses to create added value (Grant, 1996a), and it also has to possess features which are unique, difficult to transfer, and hard to replicate (Kogut & Zander, 1992; Spender, 1996; Grant, 1996a; Grant, 1996b), all of these being features which are recognised as being the sources of SCA.

The lack a solid operational definition for SCA and knowledge about how a network environment can enhance the core competencies of a firm are some of the obstacles facing the further development of the SCA theory (Hoffman, 2000).

BALANCED SCORECARD

The BSC concept assumes that competitive advantages are generated not only by factors that can be quantified, but that they are also derived from intangible assets, such as intellectual property, knowledge and skills of employees or customer relationships, which must be measured and managed. Traditional performance measures are insufficient to gauge performance and guide organisations in today's rapidly changing and complex economic environment. BSC recognises the rise of intangible assets in value creation, and the limitations of financial measurements in guiding organisations to the future. BSC is an alternative approach that balances financial and operational measures and which allows an organisation to control its organisational performance in a multidimensional concept. As defined by Kaplan and Norton (1996), BSC translates an organisation's mission and strategy into a comprehensive group of performance measures, providing the framework for a strategic measurement system, using a balanced set of measures for both financial and non-financial performance, which are linked in a cause-and-effect way, which is organised into four perspectives.

The Balanced Scorecard concept evolved over time. It was initially proposed as a performance

measurement system, and it then developed to being a more comprehensive performance management system. Today it is a strategic management system for managing organisational performance (Brudan, 2008; Andersen et al., 2001). Kaplan and Norton (2001) introduced five principles to keep the focus of management processes on organisational strategy:

1. **Strategy Translation Into Operational Terms:** A good strategy implementation needs a good understanding and internal adoption.
2. **Organisation Alignment With the Strategy:** Organisational performance is more than just the sum of its parts; all individual strategies should be linked and integrated into a single strategy.
3. **Daily Tasks Performed and Aligned With the Strategy:** BSC is the communication tool used by executives and managers to reach their employees.
4. **Strategy as a Continuous Process:** strategy should always be linked to the budgeting process.
5. **Executive Leadership Should Mobilise Change:** Executives and managers have a crucial role to play in the mobilisation process.

The BSC approach contributes to enhance firm's performance and SCA, by enabling four main elements that make the difference in the strategic management and learning when compared with other frameworks (Kaplan and Norton, 2007) (Figure 2), namely the following:

1. Clarification of the vision and the mission for all employees within the organisation;
2. The role of communication as an integration factor of all individual business units' efforts to meet the objectives;
3. Focus on the scorecard's importance as a tool that enables the revised strategy.

4. Focus on strategic feedback, by incorporating professional knowledge about the changes in the competitive environment.

Recently developments have taken BSC to being an *Execution Premium system* (Kaplan and Norton, 2008), which enhances the integration of strategy into a company's operations. This new BSC version is based on a continuous improvement approach and includes six phases:

1. Developing strategy based on the internal context, the external context, and the existing strategy.
2. Planning the strategy by developing Strategy Maps.
3. Aligning all the initiatives with the organisational strategy.
4. **Planning Operations:** Budget and strategy should be linked.
5. **Monitoring and Learning:** Both the strategy and the operations are reviewed in meetings.

6. **Testing and Adapting:** Checking if the strategy is being carried out and making the necessary modifications.

The emergence of Strategy allows organisations to describe and communicate their strategies as a way of identifying the cause-and-effect relationships between different objectives in a visual way, describing the strategy that should be followed, measured and actively managed (Kaplan & Norton, 2000). How the organisation will change is described by the strategy map. The strategy map frames its balanced scorecard in order to support the strategy and to explain from various perspectives what will be different and how the organisation will change. More importantly, strategy maps explain the underlying drivers of change. Currently, the strategy map and the cause-and-effect attract considerable interest among practitioners and firms that are developing their BSC based on the strategy map (Kasurinen, 2002).

Later writings suggested that the BSC may also facilitate the management of intangibles and serve as the basis of managing competing stakeholder

Figure 2. Managing strategy
Adapted from Kaplan & Norton, 1996a.

objectives (Kaplan & Norton, 2001, 2004). Despite its worldwide success in many organisations, BSC has drawn criticism, particularly from an extensive range of academics. The most important criticisms relate to the following:

- The causality relationships between the areas of measurement in the BSC (Nørrekelit, 2003; Akkermans & Van Oorscht, 2005).
- It neglects the dimension of time (Nørrekelit, 2003).
- BSC's reliance on a limited number of measures (Akkermans and Van Oorscht, 2005; Hudson, Smart, & Bourne, 2001; Mårtensson, 2008).
- The lack of integration between top-level and operational levels' measures (Akkermans and Van Oorscht, 2005; Hudson, Smart, & Bourne, 2001).
- An excessive emphasis on those internal processes that address external processes (Akkermans and Van Oorscht, 2005; Nørrekelit, 2003).
- The BSC concept, without modifications, is not effective enough to contribute to corporate sustainability (Bieker, 2003; Akkermans and Van Oorscht, 2005).

FUTURE RESEARCH DIRECTIONS

Sustainability Balanced Scorecard (SBSC)

Innovative business performance measures are mainly based on non-financial measures, such as operational measures, which can be used by managers during their decision-making process. Scholars of the field of sustainability management have identified BSC as being a promising management tool for the development of performance measures that combine sustainability and management in an integrated framework. The concept called the Sustainability Balanced Scorecards (SBSC) was developed with the goal

of the integration of non-monetary factors related to the current environmental and social challenges (Bieker & Waxenberger 2002; Epstein & Wisner, 2001; Figge et al., 2001, 2002a, 2002b; Schaltegger 2004; Schaltegger & Wagner 2006a, 2006b). Improving on the classical BSC by adding environmental and social components, represents an important step in promoting the concept of corporate social responsibility. The inclusion of sustainable development dimensions requires the extension of existing BSC perspectives, as well as a set of indicators. BSC has the ability to integrate intangible and qualitative aspects, but needs further development in order to become an integrated system for the management of corporate sustainability. In this research context, different approaches have been developed in order to enable SBSC to incorporate the main factors of sustainability in a measurement and performance management system (Bieker & Waxenberger 2002; Epstein & Wisner 2001; Figge et al., 2001, 2002a, 2002b, 2003; Schaltegger & Wagner 2006a).

Conceptually, sustainability management using BSC seeks to address the problem of corporate contributions to sustainability in an integrative way. It posits that in order for companies to be able to contribute to sustainable development, it is desirable that corporate performance improves simultaneously in all three of the dimensions of sustainability – economic, environmental and social. However, the practical use of BSC in the field of sustainability is a relatively new concept when compared with other systems. The research into how environmental issues can be integrated into the core business process through the extension of BSC is still at a very early stage. Results will open the door for future studies to consider the role of BSC as a performance management system which is able to include both social and environmental issues.

Balanced Scorecard in Healthcare

The review of the literature by Banchieri et al., (2011) found that more than 30% of papers

produced during the last years were applied to the healthcare industry. The implementation of Balanced Scorecard in the healthcare sector experienced many common factors when compared with its implementation in other sectors, although some challenges unique to healthcare exist. This is not surprising, as it is acknowledged that healthcare is one of the most complex industries (Marr & Creelman, 2011). One reason for the relatively slow assimilation of BSC in healthcare organisations is that they have traditionally relied heavily on the use of non-financial statistics, and therefore most healthcare organisations believed that they already possessed tools similar to Balanced Scorecard (Kocakülâh & Austill, 2007). In a comprehensive review, Zelman et al., (2003) show that Balanced Scorecard has been introduced across all areas related to healthcare. It is not only used for strategic management at an organisational level, but it is also used as an evaluation tool for: health programmes, the quality of care, improvement projects and also measuring performance in many hospitals (Zelman et al., 2003).

Inamdar et al., (2002) found that the main reason for its extensive implementation was a planned response to external forces, namely increasing financial pressures that motivated organisations to search for more effective and relevant strategic management tools than those which they were currently using.

Several authors have highlighted the benefits of using Balanced Scorecard for healthcare:

- The clarification of strategy and a framework for decision-making (Inamdar et al., 2002);
- Focus and alignment throughout all levels of the organisation (Chang et al., 2008);
- Quality improvements in patient care and outcomes (Aidemark & Funck 2009);
- Facilities a move from measuring performance to managing performance (Gottlieb, 2008);

- Enhances focus on customer service (Kocakülâh & Austill, 2007).

CONCLUSION

Value creation is the ultimate goal of an organisation. In the 1970s, Porter recommended that, in order to perceive the market position, one needs to look at the five competitive forces that affecting a company and its ability to earn above-average profits. The RBV approach suggests building a company around its core competencies. In the post-industrial world, the benefit from most traditional SCA strategies may already have been, or is about to be, eliminated. The competition can easily achieve economies of scale, and process improvements can easily be copied, although customer loyalty is harder to maintain as customers are constantly confronted by new products and services. Due to the diversity of challenges faced by organisations today, globalisation and multi-cultural factors keep pace with technological developments in an increasingly demanding and competitive environment, and thus it is unlikely that a simple qualitative approach can be universally applied, no matter how full it is of insight. In most industries, some firms are more profitable than others, regardless of whether the average profitability of the sector is high or low. Same organisations possess something special that is hard to imitate and which allows them to outperform their rivals. These unique and special skills and assets are known as resources, and they are the sources for SCA. In Porter's view, sustainability is achieved when the advantage resists the erosion of concurrency.

Corporate social responsibility and sustainable development are both issues that have recently become greatly exploited, on account of their importance for business success and the competitiveness of organisations.

SBSC helps to address different environmental and social aspects that are related to their relevance for the implementation of strategy and their execution at a business unit or company level

Future research should refine certain areas in order to give more insight into the following: strategies of successful leadership teams, success factors that provide flexibility, innovation and creativity, development of more trustworthy customer relationships, strategies development for new technologies, and human capital management.

KEY TERMS AND DEFINITIONS

Competitive Advantage: An advantage that a firm has over its competitors, allowing it to generate greater margins and/or retain more customers than its competitors.

Dynamic Capabilities: Higher order strategic processes that integrate, recombine, and generate new technological and marketing capabilities, which in turn increase firm performance.

Knowledge-Based View: Considers knowledge as being the most strategically significant resource of the firm.

Porter's View: An approach that focusses on the positioning of the organisation's business or brand in the marketplace to the best advantage.

Resource-Based View: Supports that resources possessed by organisations allow the obtaining of competitive advantage, and lead to superior long-term performance.

Sustainable Competitive Advantage: Company assets, attributes, or abilities that are difficult to duplicate or exceed; and to provide a superior or favourable long-term position over competitors.

M

Transformational Leadership for Academic Libraries in Nigeria

Violet E. Ikolo

Delta State University Library, Nigeria

INTRODUCTION

Rapid changes brought about by the information age have required that libraries re-invent themselves in order to maintain their relevance in the academic community. Specifically, libraries have had to contend with changes such as dramatic increases in the cost of library materials while budgets continue to decrease; new digital formats and communication technologies and improvements in information availability (Weiner, 2003).

The university librarian, who is the head in every academic library is required to be the executive administrator, in charge of the planning, administrative and budgetary functions of the library. However, times have changed and there is an increased call for leaders who possess, communicate, and implement a vision for transformed and improved academic libraries. It is believed that the approach the university librarian adopt in directing, guiding and controlling the staff under him/her determines the pace of progress in their libraries. However, not all leadership styles are suitable for the task of provoking or fostering innovations within the academic library.

Objectives

It is the objective of this chapter to:

1. Explore the current changes evident in academic libraries;
2. Define transformational leadership;
3. Identify the practices of transformational leaders;
4. Focus on three areas where transformational leadership can apply in academic libraries in Nigeria and;
5. Suggestions on how the future transformational leaders in librarianship can be nurtured.

BACKGROUND

It is a well-known fact that the traditional mission of academic libraries has from the beginning been to select, collect, preserve and create access to intellectual resources that can promote academic studies and research. "As a result, it occupies a central and primary place in the university, because it supports all the functions of a university with respect to teaching, research, extension of the frontiers of knowledge and the transmission to posterity the learning culture of the present and past" (Lippincott, 2005).

However, the demand and expectation placed on academic libraries have changed over time. Reasons being that technology has changed the expectations of library patrons; today, people expect to be able to find and access information from wherever they are. Libraries are now hubs of technology while offering services that have become extremely complex and sophisticated (Afolabi, 2014). Bazillion (2001) stated that electronic information sources have quickly established a formidable presence in academic libraries.

Furthermore, libraries have to implement increasingly complex solutions that involve distributed networking and access to remote information resources. The use of information technology in libraries has tremendously increased due to its

enhanced user satisfaction, cost effectiveness, faster and simpler programs, rapid communicative interaction and easier operational procedures (Storey, 1995). Another typical change that has evolved in today's academic library is in the form of library access. A library card today gives more than just access to books and periodicals at the local library; it gives access to the world just about any location. It also gives access to computing and networking technologies, in all their various forms. Some latest technologies used in academic libraries include internet access and web access to library resources which are an integral part of almost all library services (Rendon, 2014).

In the light of the glaring proliferation of information and information technologies, Germano (2011) pointed out that library managers now grapple with the demands of an increasingly complex and change-laden information landscape which offers patrons seemingly unlimited choices. Most libraries now risk becoming competitively-disadvantaged when compared to other technologically-mediated, user-defined information retrieval choices that are newly available. Critical to this seeming shift in the academic library's identity is leadership.

Townley (2003) defined leadership as mobilizing people to get things done. It involves motivating people and managing resources. Martin (2015) believes that leadership is the link between "intention and outcome. Yukl (1998) gave a comprehensive definition of leadership as the process whereby an individual member in a group or organization influences the interpretation of events, the choices of objectives, strategies, the organization of activities, the maintenance of cooperative relationships, the development of skills and cooperation from the people outside the group or organization. Library leadership has traditionally focused on structural forms of leadership by creating organization structures that support organizational goals (Schwartz, 1997). More recently, the focus is now on the library leader who is uniquely positioned to understand the value of the library and how the library serves

its parent institution while preserving and supporting foundational library values that enable that service (Hinchliffe, 2011).

In the light of the foregoing, it can be surmised that the level of effectiveness of a library leader can be measured by the value of services rendered to users, and the productivity of the library staff, which in turn relies on the leadership style employed, (Ogbah, 2013); hence, Obiwuru, Okwu, Akpa and Nwankwere (2011) noted that leadership styles are predictors to leadership effectiveness whereby leadership style in an organization is one of the factors that play significant role in enhancing or retarding the interest and commitment of the individuals in the organization.

TRANSFORMATIONAL LEADERSHIP

Inspired by Burns' (1978) notion of the transformational leader, Bass (1985) extended and developed transformational leadership theory and placed it in the context of work organizations. Transformational leaders are those who have a strong sense of direction (vision), which they communicate in inspiring ways. They are charismatic and elicit emotional responses and trust from followers. In addition, transformational leaders are said to raise follower self-confidence and self-efficacy (Shamir, House, & Arthur, 1993). Transformational leadership is a leadership style that seeks positive transformations "in those who follow" (Geib & Swenson, 2013). Simola, Barling, & Turner (2012) defined transformational leadership as a type of leadership in which interactions among interested parties are organized "around a collective purpose" in such a way that "transforms, motivates, and enhances the actions and ethical aspirations of the followers."

Apart from seeking to create positive change in their followers, a transformational leader enhances the morale, performance, and motivation of the employees, inspires change driven by a strong purpose, and is able to create a culture of trust and innovation within the organization (Tedford

& Lock, 2012). The following are the characteristics of transformational leaders as proposed by (Johannsen, 2014):

- **Keep Their Ego in Check:** Advocates the importance for the leader to keep their ego under control and not let it interfere with the best interest of their team or the organization.
- **Self-Management:** Ability to achieve results through others and avoidance of obsessional and workaholic.
- **Make Difficult Decisions:** Requires the courage to sometimes make hard decisions with a clear focus on the values, vision, objectives, and goals of the organization.
- **Inspirational:** The ability to motivate others to rise to the occasion is a key attribute that help to achieve the organization's goals.
- **Entertain New Ideas:** The ability to open up or be receptive to new ideas.
- **Adaptability:** The ability to adapt to change, new situations, and seek creative ways to respond to the dynamic business environment.
- **Proactive:** The ability to think outside the box and take an active role in growing the organization.
- **Lead With Vision:** The ability to have a set of realistic and achievable vision and then communicate this vision effectively, as well as inspire a sense of commitment and purpose.

Transformational Leadership Practices

Going by the glaring technologically characterized library environment, transformational leadership can be referred to as the act of getting extraordinary things done; often in extraordinary times. The Urban Libraries Council (2012) stated that the essence of leadership is establishing a vision and translating it into reality. While focusing on the

library leader's vision for the library, it is imperative to identify five practices that transformational leaders use to lead their followers as spelt out by Kouzes and Posner (2007). They are:

- **Modeling the Way:** Simply put, this involves leading by example. Townley (2003) states that it has to do with earning the right and respect to lead through direct individual involvement and action. How does a transformational leader model the way? They make sure that the followers know the leader's guiding principles and can use them to create effective plans. Also, character and credibility are essential to successful leadership modelling. According to Urban Libraries Council (2012) library leaders are stewards of the library's reputation as a trusted, safe, reliable, and welcoming community resource. The second step in modeling the way is affirmation of values through actions. A leader personifies their values by spending their time and attention addressing what is important to those values. They ask purposeful questions and seek feedback. And leaders teach others how to model the way by creating opportunities to discuss values. Dawson and Lewis (2007) advised that transformational leaders should earn respect and trust by demonstrating the behaviors sought from others, to be reliable and to demonstrate.
- **Inspiring a Shared Vision:** Vision in leadership is the process of forming a mental image in order to set goals, make plans, and solve problems that guide the organization into the future. This is vital when leading people. Vision is all about translating dreams to reality. By articulating a vision, the leader takes the risk that the vision may not happen and may result in discredit. Research has shown that a clearly articulated vision can draw even more commitment from people than charisma

(Urban Libraries Council, 2012). The leader must be able to see new possibilities and how they fit into the library, e.g. new technologies, convergence with other sectors such as education, the ability to anticipate users need and recognize obsolescence of a service as well as an information bearing resource before the users do.

- **Challenging the Process:** This third practice of transformational leadership has to do with courage. The courage rely solely on professional instincts not knowing exactly how things will turn out. To be able to challenge the process, a leader needs confidence and optimism. According to Stark (2012) “an organization cannot rise above its level of leadership.” This means that leaders’ attitudes set the tone for those who follow them. People will not follow leaders who lack confidence in their ability to survive a negative situation and improve the condition of the organization. Library employees want to work for a leader who truly believes that the tomorrow of the library where they work is going to be even better than it was today, and that the leader is taking the necessary actions to turn those beliefs into a reality.
- **Enabling Others to Act:** This has to do with team work, corporation among colleagues and co-library staff. Enabling others is making it possible for others to do good work through development, and trust. Enabling others also involves encouraging people to work together in learning communities. Transformational leaders create situations which lead to organizational and personal growth. They give room for other to make their own decisions and assume responsibility for their decisions. As observed by Kouzes and Posner (2007) “Leadership is not a solo act; it is a team effort.” In a world that is doing more with less, competitive strategies lose to collaborative strategies. A transformational

leader fosters collaborations by creating a climate of trust, facilitating positive interdependence and supporting interpersonal relations. He also dispels and discourages a climate of gossip and envy by verifying all information before acting on them. The transformational librarian encourages creativity and the birthing of new ideas in the library operations by carefully weighing the various opinions, inputs and suggestions from staff in the library, he/she doesn’t see himself as having a monopoly of knowledge. On the other hand, the reward for positive performance could be opportunity for capacity building through further studies, trainings and re-training, attending conferences, etc. The reward system imbedded in the transactional leadership style also encourages healthy competition among staff of the library (Segun-Adeniran, 2015).

- **Encouraging the Heart:** Encouraging the heart is about supporting individuals and groups to achieve their vision (Kouzes & Posner, 2007). Transformational leaders are cheerleaders for the people in their organizations. They acknowledge the contributions of individuals and groups. And they celebrate the victories in the organization. According to Townley (2003) there has been far too little use of this leadership practice in academic libraries. Motivation of library staff can be a good way for a transformational leader to encourage them. Research has conclusively shown that engaged employees are more productive and satisfied (Maxwell, 2013). A transformational leader encourages his followers to take part in job training exercises. The followers then become well equipped and have the necessary skills and abilities to do their jobs while helping the library achieve its vision. Transformational leadership also includes looking for leadership potential in others. By developing leadership skills the

transformational librarian creates an environment where other librarians can continue success in the long term, which is a true measure of any grate leader.

AREAS TRANSFORMATIONAL LEADERSHIP CAN APPLY IN ACADEMIC LIBRARIES IN NIGERIA

While decrying the fact that transformational leadership has not been widely adopted and practiced in libraries, there are potentials for academic libraries in Nigeria as their leaders seek to create increased relevance within the life of the academic community. It is perhaps in this regard that it is eminent to point out the areas that Nigerian academic library leaders need to focus more in the transformational leadership discuss:

- **Vision:** Transformational leadership is a vision propelled type of leadership. More than anything else, academic libraries in Nigeria require visionary and innovation driven leaders. A primary part of a transformational leader's vision for the academic library must be focused on identifying renovations that would encourage better use of the library. According to Bill Gates's quote on transformation –“you need to see your service is obsolete before the customer does. The only companies that succeed will be those who obsolete their own products before someone else does.” This means that library leaders must have the ability to anticipate the library users need and recognize obsolescence before the users do. Also, the ability to recognize that something new is needed instead of more refinement of what exists already. Library leaders don't have to wait for users to stop using library services or for them to register complaints to know that there is need to improve services.
- **Courage:** This is one quality that academic libraries in Nigeria desperately need in their leaders. It is of little wonder that.” Matthews (2002) stated that “leadership of tomorrow's academic libraries is not for the faint of heart. The library leader must have the courage to face and convince management of Nigerian tertiary institutions of issues pertaining to innovations in the library. In the face of the globalization, academic libraries in Nigeria are confronted with a unique set of problems. Like the financial resources with which to meet increased demands for access to both print and electronic resources, library staffs requirements of a new set of skills that will enable them survive and practice in the new digitalized collections. There is also

Academic libraries need transformational leaders whose confidence and optimism will not deprive them from entertaining new possibilities and suggestions from others. For instance, at the Z. Smith Reynolds Library at Wake Forest University, Tedford, and Lock (2012) stated that the library leader wanted to keep the library open for twenty-four hours a day during exam week (a practice initiated at the Undergraduate Library at Wayne State some years before), which required additional staffing and shifting staff hours. First, the transformational library leader modeled the way, volunteering to stay extra hours and issuing a call for four other volunteers to stay overnight. Thirty people stepped forward. Such an overwhelming response epitomized the alignment between change and the longstanding service culture of the organization and how Sutton's modeling the requested behavior affected the ability to make the change. Again, “Wake the Library” was repeated for the exam weeks of Fall 2006 and Spring 2007, providing the necessary data to recommend a permanent change to remain open twenty-four hours a day for five days a week.

the issue of the acquisition of electronic resources, along with its attendant problem of adequate bandwidth and the cost of keeping technology current. Again, there is the constant reminder of the problem of inadequate power supply without which none of the a 21st century academic library services can succeed.

According to Okiy (2010), of all the different types of libraries in Nigeria, only university libraries have a clearly defined policy of funding, because the National Universities Commission (NUC) has a statutory provision that at least 10% of the recurrent annual budget of the parent institutions should be allocated to the library. It is however sad to note that most University libraries still face the challenge of financial constraint. It is regrettable that such monies are not forthcoming as most university administrations tend to flout or fail to comply with this provision (Fabunmi, 2004; Okiy, 2010).

There seems to be less confidence on the part of library leaders about stirring things up with their parent organizations, this can result in the postponement of timely transformation or a loss of opportunity that puts the whole academic library at the risk of losing its significance in the academic community. Hence, transformational leaders require the guts to demand for what belongs to the library in the first place, which might involve being adamant and refusing to back down.

- **Communication:** The ability to communicate well is very germane to fruitful relationship and success of a leader. Giving relevant and timely information as well as the expectation of feedbacks from stakeholders are desirable (Fadehan & Oluwasanmi, 2010). One of the most important areas where communication may be affecting academic libraries in Nigeria is between the library and the campus community. Most often the campus community has little or no idea of the library's value in

their educational mission, the services offered and the overall support the academic library can provide to them. By demonstrating and communicating value exercises, transformational library leaders can influence the academic community and the parent organization.

Furthermore, the leader will have to recognize and tap into the problem-solving skills of all staff as well as external experts. This can only be pulled off with good communication skills of the library leader. Effective channels of communication such as holding of sectional meetings or talking with other library staff on a one-on-one basis can be employed. Also, the library leader can harness positive outcomes and performance indicators, and with the data collected can clearly articulate the value of the library to the parent institution. In addition, Sweeney (1994) stressed the fact that the transformational library leader must also play the role of a superb communicator who listens well, speaks and writes well. This leader must articulate concepts that are new and foreign to staff, users, administrators, and others in an appealing and rational manner.

NURTURING FUTURE TRANSFORMATIONAL LEADERS IN LIBRARIANSHIP

It is a well-known fact that you cannot give what you do not have, similarly, it is believed that the most successful leader will have developed his or her leadership skills over a long period of time. Hence, for future transformational library leaders to develop the following suggestions could be considered:

- **The Leader as a Mentor:** Perhaps this is the most important means of nurturing future transformation librarians. There are a lot of experienced and seasoned library leaders in Nigerian academic librar-

ies, however, not many of them practice the transformational leadership style. The few who do and have results to show must identify talented new individuals and even older library leaders and help them develop the qualities necessary for success in an environment of ambiguity, and providing productive learning experiences that build on existing strengths and minimize weaknesses.

- **Internship Programs:** The two major bodies of librarianship in Nigeria also has a part to play in the issue of nurturing future transformational leaders for the libraries. The Nigerian Library Association (NLA) and the Librarians Registration Council of Nigeria (LRCN) can organize leadership apprenticeship programs. Programs that can afford younger librarians opportunities to periods of internship with a particular transformational leader so that they can learn informally about what it actually takes to lead the modern day academic library. The NLA or LRCN can also use this sought of program to inspire younger librarians who excel at national or local competitions organized by the bodies. These governing bodies can also confer awards on libraries and library leaders in recognition of outstanding leadership in academic libraries.
- **Formal Transformation Leadership Training at Library Schools:** Here, in the library schools more than anywhere else is the awareness that the required skills to excel by students who are potential library leaders are constantly changing. This means the skills needed by library leaders are changing. Bass (1990) posits that transformational leadership skills can be learned, and plenty of methodologies to can also be found in literature. Curriculums of library schools should be upgraded especially at the postgraduate levels on the ideal qualities required of library leaders,

knowledge of these qualities can inform how well LIS programs prepare the future leaders of the field. Examples of such leadership courses on Leadership Programs developed by LIS schools and libraries to foster leadership skills in MLIS students and practicing librarians in the U.S. are The Library Leadership and Management's (LLAMA) Development division has created an annual seminar called the Leadership Development Seminar, which is held each year during ALA's Midwinter meeting (Considine, 2011).

- **Building a Knowledge Transmission Infrastructure:** The Nigerian society is well known for its oral traditions. Records of transformational solutions to innovative problems can be kept by the library leader for future reference and for upcoming leaders. Thus the use of more unobtrusive methods can be applied where leaders should be observed in their work place, while performing their day-to-day activities, when the knowledge needed to learn and perform tasks within a complicated process is written, updated dynamically, and shared using the technology infrastructure, then the knowledge needed to perform a job is not only in someone's head, but also well documented and stored.
- **Leader Followers / Followers Leader:** Today's leaders were once followers, similarly, today's follower can be tomorrow's leader. Academic librarians in Nigeria must be ready to invest in themselves. Librarians should put more efforts into understudying their leaders so that they too can be better prepared to take over the mantle of leadership in their libraries.

CONCLUSION

It is obvious from the foregoing that the traditional mission of academic libraries will never change,

however the means of achieving this mission must change. In order for Nigerian academic libraries to continue to build and sustain their position as active, trusted, and responsive agents of change in the academic community, they need transformational leaders who will move their libraries forward with vision, courage, purpose, and determination. The academic library of tomorrow needs a leader who is will not be afraid of the changes that are eminent in their libraries, but will encourage the followers to think, speak and act. A leader who is willing to take risks with innovations in information technologies in order to better information service delivery in libraries and one who will be bold to face management with convincing arguments in favor of the academic library, the librarians working in it and everything it stands for.

FUTURE RESEARCH DIRECTIONS

Although this chapter has attempted to shed light on important aspects of innovation in academic libraries, transformational leadership practices and the areas that Nigerian academic library leaders need to focus on, a major limitation is that the literature did not cover a qualitative or quantitative perspective of transformational leadership practices in Nigerian academic libraries. Further research on transformational leadership in academic libraries should cover areas such as the important leadership profiles, including personal competencies, which might facilitate or inhibit innovation in academic libraries. Empirical studies should be conducted on the effects of transformational leadership on staff productivity in academic libraries in Nigeria, as well as a study on the direct effect this leadership style will have the innovativeness of academic libraries given the unique circumstances these libraries face as regards availability of funds.

Marketing

Are Social Marketing Investments Used as a Tool for Voluntary Reporting or Disclosure?

M**Tugba Ucma Uysal***Mugla Sitki Kocman University, Turkey***Ganite Kurt***Gazi University, Turkey***Ali Naci Karabulut***Mugla Sitki Kocman University, Turkey*

INTRODUCTION

The need to respond to conditions that change with the effect of social transformation in line with the globalization phenomenon and developments in information technologies, have resulted with the development of new corporate behavioral patterns of enterprises. It is possible to observe these behavioral patterns both in terms of reporting activities and also in terms of marketing activities. The sustainability and corporate governance concepts that are being applied in businesses in an increasing manner stand for the cumulative efforts for accountability or a convergence. Because, as long as sustainable reporting of businesses are questioned, the meaning and nature of accountability are manifested. This in return is associated with the sense of transparency of businesses (Kolk, 2008) and even stands for the voluntary reporting of non-financial information.

On the other hand, if the situation is assessed in terms of marketing activities, it is possible to observe a similar evaluation to the assessment made in terms of reporting. In other words, the accountability of the business concept is once more in front of our eyes. Because, a number of issues such as air pollution, deterioration of public health, wasting of natural resources, economic stagnancy, inflation, unbalanced income distribution etc. that

are experienced due to increasing population at the global level and volume of production result with the questioning of businesses and modern marketing approaches by the people (Clifford, 1998; Drucker, 1974; Doğaner, 2011; Torlak, 2006; Yükselen, 2014). Furthermore, people have become more aware of illegal and unethical behavior in financial and legal presentations (Salimbene & Ferrera, 1996) believing that both stakeholders and non-stakeholders of organizations have the right of information on specific social agenda (Miles & Munilla, 2004).

There are a number of definitions for what sustainability reports stand for of which the importance is being emphasized at many points. But to this date, there is no globally accepted definition of corporate social responsibility (CSR) or sustainability reporting. However, a common European understanding of what CSR means has emerged on the basis of the European Commission definition of CSR as “*a concept whereby companies integrate social and environmental concerns in their business operations and in their interaction with their stakeholders on a voluntary basis*” (The Council and the European economic and social committee 2006, Dilling, 2010). Or these reports are being expressed as follows in the general sense and their relation with CSR concept is being underlined in the definition.

Sustainability reporting can be considered as synonymous with other terms for non-financial reporting; triple bottom line reporting, CSR reporting, and more. It is also an intrinsic element of integrated reporting; a more recent development that combines the analysis of financial and non-financial performance. (<https://www.globalreporting.org>)

Sustainability reporting encompasses a process that gives way to the forming of a relation between the enterprise and the society (Porter & Kramer, 2006). Voluntary reporting and disclosure are thus being used as a reporting process that reduces the amount of asymmetrical information between the business and stakeholders (Verrechia, 2001) and is being supported by means of a set of social sanctions. Social problems that emerge in the global scale have given way to the development of new social standards for the sustainability of organizations (Drucker, 1974: 337-338; Doğaner, 2011: 27; Torlak & Barca, 2012: 21; Wasik, 1996). The business community has to yield reasonable profits for stockholders and owners on one hand, while supplying decent products at reasonable prices, honest advertisements, fair treatments and profitable opportunities to employees, customers, suppliers and competitors with a strong sense of responsibility to the communities it inhabits and serves on the other hand (Gini, 2005; Pava, 1998). A distinct marketing discipline has emerged since the early 1970's which is called as social marketing which is more comprehensive than modern marketing and which refers primarily to efforts focused on this kind of social issues (Lee & Kotler, 2011; Doğaner, 2011). Therefore social marketers are primarily concerned with social issues and financial consequences of their actions only to the extent that they want to insure their organization's financial viability (Bloom & Novelli, 1981).

Investments in social marketing which were deemed as implementations that bring forth additional costs to organizations at the outset can actually be used as efficient tools in terms of voluntary reporting and disclosure of organiza-

tions. In this context, this chapter aims to find out if social marketing investments are used for voluntary reporting or disclosure by examining the websites of the companies which are ranking in the Turkey ISE 100 Index with Structuring Content Analysis method. Investigating the only way of voluntary reporting is the limitation of this study even though websites are the primarily disclosure instruments for the companies.

THEORETICAL BACKGROUND

According to the accounting literature, it is observed that these studies coincide with early 1990's (Lamberton, 2005). The measurement of social effects of these costs in particular and the reflection of these effects to reporting constitute the starting point of social accounting implementations (Aras & Crowther, 2009). Taking a look at the studies within the scope of said literature, it is observed that the relation between corporate social responsibility and financial performance is being focused upon in particular. Global Reporting Initiative (GRI) was established in 1999 to publish CSR reporting standards which is the sole system aiming to fill the gap in related literature and a model was presented to the US financial reporting system. GRI provides a standardized approach as an aid to reporting of sustainable information. GRI has also turned into a framework with the highest level of acknowledgment worldwide for voluntary reporting.

GRI is effective for the reporting of corporate social responsibility projects or voluntary reporting activities of businesses besides marketing strategies. One of the reasons for this is the fact that CSR is an important communication tool for stakeholders to have access to necessary information. Another reason is listed as the influence of CSR on the reputation management and brand protection activities of enterprises (Nikolaeva & Bicho, 2011). Important information is provided for social or environmental disclosure from variants obtained from markets. For instance, it has

been determined upon studies conducted by Gray et. Al. (2001) that corporate characteristics of businesses have directly affected the social disclosure levels of these companies. Kolk (2003) had at first scrutinized the sustainability reporting trends of companies listed under Fortune Global 250 and had later on made research on the reporting levels of multi-national companies within the framework of accountability, corporate governance and understanding of sustainability in 2008. Hedberg and Malmberg (2003) on the other hand made research checking if the GRI and CSR reports made any contribution to the reliability of Swedish companies. Gray (2006) made a research checking if sustainability reporting of companies had any effect on the development of corporate behavior. Brown et. al. (2009) studied the effects of the sustainability reports prepared within the framework of the GRI on the institutionalization of companies. It has been found if sufficient information can be obtained on corporate sustainability levels when corporate sustainability reporting is made within the framework of GRI upon studies conducted by Isaksson and Steimle (2009). Also, a critical analysis was made in studies conducted by Fonseca (2010) checking if sustainability reporting made by companies in the mining sector has contributed to the reliability of companies besides external trust.

According to the marketing literature, several studies can be traced since the 1960's on issues that are named as social marketing in present day but the origins of the term social marketing can be traced to Kotler and Zaltman's classic 1971 article titled "Social Marketing: An Approach to Planned Social Change" (Andreasen, A.R., 1994). In this article, authors were examining the applicability of marketing concepts and techniques to the promotion of social objectives and they were defining the social marketing as: "the design, implementation, and control of programs calculated to influence the acceptability of social ideas and involving considerations of product planning, pricing, communication, distribution, and marketing research". Kotler, et. al (2002), defined

social marketing again as "the use of marketing principles and techniques to influence a target audience to voluntarily accept, reject, modify, or abandon a behavior for the benefit of individuals, groups, or society as a whole".

The first argumentation on the social marketing approach in terms of sustainability was started by marketing scholars in the 1970's with Ecological Marketing (Henion & Kinnear, 1976) and The Ecologically Concerned Consumer (Kardash, 1976). Fisk (1973) made a contribution to the approach of Peattie and Peattie (2009) with the "Theory of Responsible Consumption". McKenzie and Mahr (2000) make the proposition of developing social marketing programs based on the society to achieve a sustainable set of behavior for the sake of the organization. Andreasen (2002) explains how the social marketing approach can be used as an active marketing tool according to social changes in the target audience. Peattie and Peattie (2009) focuses on the fact that the social marketing approach can be used as a tool in reducing consumption levels targeting a sustainable life.

MAIN FOCUS OF THE ARTICLE

Only one previous study (Kurt & Ucma Uysal, 2014) examined sustainability reporting for voluntary reporting or disclosure in Turkey. It found that sustainability reporting can be best framework for voluntary reporting and disclosure in Turkey. The aim of the present study is to use the methodologies of previous studies (Brown et al., 2009; Kolk, 2003; Kolk, 2004; Kolk, 2008; Simnett et al., 2009; Kurt & Ucma Uysal, 2014) to explore social marketing investments can be used as a tool for voluntary reporting or disclosure in Turkish companies in capital markets. The voluntary disclosure levels of companies listed on the ISE 100 index are thus being clarified revealing the importance attributed by businesses to sustainable growth. At this point, emphasis is made on social marketing investments which are perceived by businesses as net increases in costs while evaluation is made on social goals

set forth by companies in terms of sustainability. The Structuring Content Analysis which was used by Isaksson and Steimle (2009) has been utilized to scrutinize sustainability reporting by Turkish companies which is one of the non-financial reporting forms. Theoretical analyses could be made by means of the type of analysis, regarding businesses that publish sustainability reports in diverse aspects and those which do not publish sustainability reports but that provide information on web pages under such title. Main assessment criteria which we have selected in line with Kolk's studies (2008) on which we have focused during the analysis and criteria in relation with social marketing investments (Steurer et al., 2008; Lee et al., 2010; Revelli & Viviani, 2015) are listed as follows:

- Separate sustainability report,
- Social, ethics and environmental reports or politics,
- Financial reports with integrated sustainability information,
- Code of ethics,
- Separate sustainability department/unit,
- Separate section on corporate governance in the report,
- External verification/assurance of sustainability reports or sustainability information,
- Sustainability content on web page and in CEO Statement,
- Socially responsible investing and social marketing and social goal.

Separate Sustainability Report

The scope of the concept of reporting has become quite extensive in the present day. Businesses have attributed more importance to social, ethical and environmental issues upon pooling of sustainability and corporate governance concepts within a single report and thus giving start to such reporting means, while the understanding of sustainability has been more inclusive also encompassing control and accountability issues

(Kolk, 2008). It has been observed that only 31 companies among those listed in the ISE 100 index have published reports titled as sustainability reports besides separate financial reports. Having taken a look at the reports of the 31 companies that have published such reports, it has been observed that each report includes disclosures on the sustainability approach of the company and the Board of Directors and the importance of such an understanding has been emphasized in terms of sustainable growth. The reports also include statements regarding the importance of value attributed to customers besides corporate governance, environmental and social responsibility projects and ethical values, and value drivers. Also the web pages of companies that have published separate reports include disclosures on issues that are listed in the sustainability report under the heading of corporate social responsibility. The other 69 companies that are listed in the ISE 100 index as of the third quarter of 2015 do not publish separate sustainability reports. It is observed that a total of 17 companies listed in the ISE 100 index published separate sustainability reports at the end of 2013, upon evaluation made together with the results obtained in previous studies (Kurt & Ucma Uysal, 2014). An increase has been observed in the number of companies that have published separate sustainability reports upon studies conducted 1.5 years later. These findings display that there has been an improvement in the reporting level of non-financial information in Turkey which develops within the framework of an understanding of corporate governance and which is expressed as integrated reporting.

Social, Ethics, and Environmental Reports/Politics

There has been an increase in recent years in the number of companies that make reporting on their environmental and social performance. It has been revealed upon research made by KPMG (2002) that sustainability reports are being prepared to encompass economic, social, ethical and

environmental issues (O'Dwyer & Owen, 2005). These reports generally encompass projects and policies implemented by businesses within the scope of their trust indices. Taking a look at the matter for companies in the ISE 100 index, it is observed that reports published by 70 companies that make separate reporting on sustainability as mentioned above, include information on said issues. Under these circumstances, it is possible to claim that 70 percent of businesses listed in the ISE 100 index either publish their environmental and social reports or policies which are deemed as non-financial reports, in their web pages or include such information in sustainability reports which are published separately.

Financial Reports with Integrated Sustainability Information

Integrated reporting stands for reporting made by companies also defining their human, intellectual, natural and social assets in addition to their traditional financial assets and their production potential. Legal and structural arrangements on integrated reporting are being put into life in the US in particular. For instance, Sustainable Accounting Standards Board (SASB) brings forth related arrangements on integrated reporting and disclosure for US companies in the industrial sector by means of new standards set forth (Investor Responsibility Research Center Institute Report, 2013). The main purpose of the presentation of financial information in studies conducted for the standardization of financial reporting worldwide is to provide necessary information to facilitate decision-making processes of all internal and external users of information on the related matter. It is being observed that a number of multi-national companies provide information on their social and environmental performances and their understanding of sustainability in the present day, to cover the needs of information of their internal and external stakeholders (Ballou et. al., 2006; Simnett et. al., 2009). Businesses are

disclosing their activities within the framework of an understanding of sustainability (Kolk, 2004) to display their transparency in particular and to build trust in their financial performance. Annual activity reports of businesses in the ISE 100 index have been accessed primarily to conduct such a study and information has been sought in activity reports on sustainability and perpetuation of the company. Such information has been found in 74 businesses within the scope of studies. It is possible to claim that serious developments have been experienced in the integrated reporting approaches of businesses compared to results obtained in previous studies (Kurt & Ucma Uysal, 2014). This is being explained by means of the development of capital markets in particular and stands as a proof that companies that are traded at the ISE are seriously prepared for such issues in the national scale.

Code of Ethics

It is observed that the presence of ethical codes that are generalized following the auditing scandals in particular and which are set forth within the own bodies of organizations, are being presented as a part of the socialization phenomenon in which businesses display ethical behavior, when assessed in terms of theory and practice (Somers, 2001). For this reason, businesses publish a set of ethical codes somehow within their own bodies and provide information on their ethical behavior as an organization for internal and external information seekers. It has been determined that 70 percent of companies within the scope of ISE 100 index have ethical codes published in their web pages. The set of ethical codes set forth by businesses are also of importance in terms of their social marketing approaches. Because, there are a number studies (Eagle, 2008; Eagle et al., 2013) that focus upon the importance of ethical codes defined by businesses for a sound understanding of social marketing.

Separate Sustainability Department/Unit

It has been studied to check if businesses have a separate sustainability department within the framework of their understanding of sustainability. It has been determined that none of the companies have a sustainability department which has been formed separately within the body of the organization. Kolk (2008) determined upon studies conducted on multinational companies that there are separate sustainability departments or units in a part of multinational companies (Ford, Shell, BP, etc.). However, such a department does not exist within the bodies of companies listed in the ISE 100 index no matter if they publish sustainability reports or not. However, it has been found out that 8 companies out of those in question have an organizational unit similar to a social responsibility committee. Such data could only be accessed through organizational charts that are entered in the web pages of the businesses in question.

Separate Section on Corporate Governance in the Report

Checking if there is a separate heading on corporate governance within the reports published by companies within the scope of said studies that publish sustainability reports separately, has been included within the scope of studies in question. It has been determined that detailed sections regarding a corporate governance approach are included in the report by 30 companies that publish sustainability reports. It is observed that corporate governance and corporate social responsibility issues are taken up as a whole in the sustainability reports of 18 companies. Businesses have set forth sustainability strategies within the framework of a corporate governance approach in terms of relations with stakeholders in particular and have expressed these strategies on basis of corporate social responsibility and accountability. Integrated reporting develops with an understanding of corporate governance for each business as a bottom

line (Smith, 2014). However, such a relation is underlined only by 30 businesses within the scope of said studies, whereas no mention is being made to such a relation in other cases.

External Verification/Assurance of Sustainability Reports or Sustainability Information

We have expressed in previous sections that reporting of social, environmental and economic performances of businesses under the heading of sustainability or the presentation of these over their web pages are being considered as voluntary reporting tools within the framework of Global Reporting Initiative. Building of external trust by companies by means of non-financial reporting regarding information users and stakeholders or verification of policies in selected issues are of utmost importance in terms of the reliability of information (Fonseca, 2010; Matisoff et. al., 2013). At this point, companies make use of various tools such as the Carbon Disclosure Project (CDP), and quality and occupational safety certificates serving to external verification and assurance. It is observed that 45 percent of companies within the scope of said studies make use of external verification and assurance in issues of sustainability reporting and sustainability in the general sense.

Sustainability Content on Web Page and in CEO Statement

It has been checked within the scope of studies if there are any disclosures made in web pages of companies and the reports published by the Board of Directors on sustainability issues. According to findings, there is content regarding sustainability issues in the web pages of 60 percent of businesses. Also, according to findings and upon a contents analysis of speeches delivered by CEO's in reports published by the Board of Directors and annual activity reports and it has been determined that statements on topics such as sustainable development, sustainable growth,

the environment and sustainable development attributing importance to stakeholders have been the most frequent expressions during the speeches delivered by CEO's of 63 percent of companies.

Socially Responsible Investing, Social Marketing, and Social Goal

The relation between the corporate social responsibility and financial performance of businesses is generally being discussed in terms of socially responsible investing (SRI) (Hill et al., 2007; Matloff and Chaillou, 2013). SRI is being described as follows by Ciocchetti (2007) in the most general sense:

SRI, refers to financial contributions into investment vehicles designed to combine the traditional investment philosophy favoring profit-maximization with a values-based component seeking non-financial benefits. Such non-financial benefits are often referred to as social returns.

As will be seen from the definition, SRI is a concept which results with costs in the short run as a values-based component to seek non-financial benefits but which positively effects the long term profitability of the company and its perpetuation. This in return constitutes a reference for social marketing which is more extensive than the traditional marketing approach of the business. Because, a number of issues such as air pollution, deterioration of public health, wasting of natural resources, economic stagnancy, inflation, unbalanced income distribution etc. that are experienced due to increasing population at the global level and volume of production result with the questioning of businesses and modern marketing approaches by the people (Drucker, 1974; Doğaner, 2011; Torlak, 2006; Yükselen, 2014). Furthermore, people have become more aware of illegal and unethical behavior in financial and legal presentations (Salimbene & Ferrera, 1996) believing that both stakeholders and non-stakeholders of organizations have the right of

information on specific social agenda (Miles & Munilla, 2004) SRI and social marketing targets emerge as tools which are voluntarily executed by businesses to express themselves to the public in a better way by means of such an interactive relation. According to study results, 58 percent of businesses listed in the ISE 100 index disclose their social responsibility investments and social marketing activities on their web pages. Taking a look at social targets set forth by businesses at this point, it is observed that the environment, education, culture & arts, sports, health and safety issues top the list in a descending manner.

FUTURE RESEARCH DIRECTIONS

Marketing and reporting activities which have become more complicated upon developments in the business world are actually outstanding phenomena that affect decision-making processes for those that implement information. The reporting of non-financial information in particular without any legal sanctions and its publishing each year in accordance with social expectations also affect the long-term profitability and brand management processes of organizations in a direct manner.

In this regard, it is obvious that, in the near future, companies will become more transparent structures that will be more willing to give detailed information on their activities. It is without a doubt that the information technologies will be the principal tools to fulfill companies' such needs. It is expected that this chapter will contribute to the scholarly literature researching on the use of information technologies as a voluntary means of communication between companies and the public, thus, constitute a starting point for future researchers.

CONCLUSION

Voluntary reporting and disclosure concepts that constitute the basis of corporate social responsibil-

ity are of utmost importance for businesses wishing to catch a competitive advantage in present day conditions and particularly within the global economic system. Such an approach shapes the marketing approach of quite a number of businesses besides including the reporting of non-financial information. Main reasons for this can be listed as the fact that sustainability reports provide answers to diverse information users besides being used as a marketing communication tool, its contribution to brand management and its effects on the development of market based intellectual property (Nikolaeva & Bicho, 2011). Each of the reasons expressed above results with the avoiding of traditional marketing approaches of businesses giving way to attributing importance to social marketing and social responsibility investments which are expressed as an understanding of modern marketing. Taking pioneering studies as basis, it is being checked if businesses listed in the ISE 100 index as disclosed in the last quarter of 2015 make use of their social responsibility investments as a tool in terms of voluntary reporting.

Websites of the companies which are ranking in the Turkey ISE 100 Index had selected as research case and examined with Structuring Content Analysis method for this purpose. Under this limitation, it is worth pointing out that businesses execute these activities with a voluntary perspective due to the lack of a legal infrastructure in Turkey regarding sustainability reporting in particular. Assessment criteria used in the previous study has been taken up once more for the contents analysis during present studies and it has been observed that each criterion displayed a change compared to the previous year. Besides these, the fact that 58 percent of businesses attribute importance to SRI and social marketing activities and furthermore publish these on their web pages besides sustainability reports is to be mentioned to underline the importance of the whole matter in Turkey.

KEY TERMS AND DEFINITIONS

Corporate Social Responsibility: A concept describing the voluntary actions of an organization for fulfilling their responsibilities towards third parties providing resources for the community and the organization.

Non-Financial Reporting: Represents voluntary provision of non-financial information by an organization for the information users constituting its external environment, including mainly its stakeholders, shareholders, investors, and partners, so that acting transparently.

Social Marketing: Is a marketing concept which seeks to influence behaviors not to benefit the company, but to benefit the society in general.

Sustainability Reporting: Represents provision of non-financial information by an organization to internal and external information users in line with the main objectives of development, in addition to an organization's transparency in terms of its performance and as well as its management approach.

Voluntary Disclosure: Represents sharing nonfinancial information, including ethical, environmental, and social issues, by an organization with internal and external information users without any legal obligation.

The Impact of Artificial Intelligence and Virtual Personal Assistants on Marketing

INTRODUCTION

As marketers and consumers simultaneously adopt Artificial Intelligence (AI) services and applications, the dynamic of the process of exchange between the buyer and seller in the marketplace is being fundamentally altered. Clearly, the Internet and social media have radically altered not only the roles and relationships, but also the differential advantages held by marketer and consumers in the marketing game, as consumers can now find (via Google) and buy (via Amazon and more recently via Facebook) anything, anytime, anywhere on the recommendation of friends and family (via FaceBook) or other customers (via Yelp) and communicate globally the transaction in 140 characters or less (via Twitter). Traditionally, marketing has been something done *to* the consumer. Products were pushed. Communication was one-way and intrusive. Commercial messages remained mostly brief, designed as much to entertain as to inform and often provide the consumer with little more than a catch phrase in the guise of a slogan or jingle. With the advent of the Internet and emergence of social media, the communication pattern of the marketing game expanded from strictly “outbound” with the marketer doing all the talking, to include “inbound,” wherein the consumer searches, contacts, and transacts with the marketer. Marketers no longer can simply buy consumers’ interest; it must be earned. Consum-

ers increasingly rely on each other for product and service information and recommendations. Rather than the customer being targeted by the seller, the seller seeks out the buyer. However, as significant and swift this change has been (given social media is but a decade old), arguably the greatest change is still to come with the advent of AI. As marketers and consumers begin to fully take advantage of what AI agents have to offer, the nature and process of the facilitating exchange in marketplace will dramatically change. As AI agents increase the knowledge and insight marketers have regarding consumers’ product preferences and buying patterns, those same agents decrease the consumers’ susceptibility to the marketer’s message and manipulation. As AI agents search, evaluate, recommend, and finalize purchases, the actual consumer may actually be removed from the final purchasing decision.

This entry will review the state of the art in AI, with a particular focus on applications in marketing. Based on the current capabilities of AI in marketing, the author’s explore the new rules of engagement. Rather than simply targeting consumers, the marketing effort will also be directed at the algorithms controlling the consumers’ virtual personal assistants (VPAs). Instead of exploiting human desires and weakness, marketing will need to focus on meeting the user’s actual needs. The level of customer satisfaction will be even more critical as mar-

DOI: 10.4018/978-1-5225-2255-3.ch499

keting will need to focus on establishing and maintaining a reputation in competition with those of similar offerings in the marketplace. This entry concludes with thoughts on the long term implications, exploring the role of customer trust in the adoption of AI agents, the security requirements for agents and the ethical implications of access to such agents.

BACKGROUND: APPLICATIONS OF AI BY MARKETERS

The term Artificial Intelligence (AI) was first coined in 1956, and has evolved over a half century of steady progress in building computers that can manipulate symbols (both logical and linguistic). In the mid 1990's, with the commercialization and diffusion of the Internet, exponential growth in computing power and advanced software sophistication fully functional intelligent agents have come to pass, and the term "intelligent agent" has been formally defined:

An intelligent agent is software that assists people and acts on their behalf. Intelligent agents work by allowing people to delegate work that they could have done to the agent software. Agents can, just as assistants can, automate repetitive tasks, remember things you forgot, intelligently summarize complex data, learn from you, and even make recommendations to you. (Gilbert, 1997)

Whether termed an agent or assistant or defined as artificial or virtual, these emerging applications are an amalgamation of many technologies – voice recognition, linguistic sciences and natural language processing, machine learning, cognitive computing, analytical and predictive statistics, neural networking, and deep-learning algorithms.

Marketers are currently utilizing an array of advanced AI platforms, services and technologies. The scope of activities and functions that AI is already being applied includes:

- Basic market research (i.e., consumer behavior and psycho-analytics),
- Media and creative strategy (i.e., media planning, message design, and pricing),
- Customer service, sales, and relationship management.

Basic Market Research

AI has already enabled marketers to understand qualitative input from surveys, in addition to the quantitative survey results. Using tools from companies like Luminoso Technologies and Kanjoya Inc., marketers can automatically analyze text input on surveys and social media platforms to understand meaning as well as the emotions of the subjects (Rusli, 2014). Marketing firms currently employ AI agents, particularly exploiting an ability of AI to simultaneously enhance both intelligence and emotion (Mceleny, 2015). With the ability to analyze structured and unstructured data from credit cards, sales databases, social networks, location data, and web pages, marketers can ascertain trends in consumer preferences and sentiments as well as calculate sales probabilities.

AI has been applied to the real time analysis of human emotions. Advanced image processing has matured to the point where emotion recognition can be done either via a webcam or using a camera in a physical setting (and emotion detection in verbal interactions has an even longer history) (Eaton, 2012). Using AI techniques, the user's reaction to a product or to an advertisement can be interpreted, and the stimulus can be modified accordingly. For example, a viewer displaying positive emotions towards the product can already be cajoled into completing a transaction (or can be shown additional positive messages to encourage the transaction), while for negative reactions the viewer can be offered more explanations (if the emotion detected is confusion or a blank stare), a different set of options (if positive and negative emotions are displayed) or a different offering altogether (if strong negative emotions are encountered).

Indeed, AI systems such as IBM's Watson has the ability to discern consumers' personalities through *Psycholinguistic Analysis* of the language a consumer uses when posting on social media sites and predict major events that are likely to happen in a consumer's life. Watson does not need to know the social media accounts of a consumer beforehand, rather the technology is able to identify a consumer's social media usage by sifting through what a consumer posts via a company database (Russel, 2014). Thus, AI is changing the scope of basic market research, opening up a new challenge for marketers to move beyond traditional strategies and tactics for identifying consumer behavior.

Media and Creative Strategy

Advancements in AI enhanced research and analytic applications allow marketer's to find, read, and analyze a consumer's every search, post, tweet, pin, video message, product evaluation, credit card purchase, media consumption preference and/or any and every other bit of information that can be gleaned in the infosphere about the consumer. Companies have already started to mine social media to understand emotions and preferences as expressed on platforms (i.e., Bluefin Labs) (See Arndt, 2011).

Artificial intelligence is being used to create custom commercial messages for individual consumers based on their user profile and media behavior. Accordingly, campaign materials are modified in real-time, to maximize consumer interest and message retention. AI agents can adjust photos of human faces to be more memorable, attractive and friendlier (Khosla, Bainbridge, Torralba, & Oliva, 2013) as well as popular online (Khosla, Sarma, & Hamid, 2014). Similar technologies could be used in real time to optimize the light and presentation of a product in an ad, based on aggregated user reactions to the ad. "Dynamic Creative Optimization" technology is also being used by marketers to customize promotions and pricing. However, marketers should remain cog-

nizant of the risk of adjusting "prices on the fly" (i.e., Amazon) (See Gunderson, 2012).

The predictions is AI driven "Dynamic Creative Optimization" could be responsible for as much as 40–50 percent of all promotional messaging and advertising within the next ten years. As proclaimed by the media and communications agency PHD, inevitably "Algorithmic-driven creative and knowledge-driven targeting will open up the potential to move beyond segmentation and focus on individual level messaging—so each person has a communication targeted specifically at them based on their unique situation (what they know, what they like, category purchase propensity, the brand purchase propensity, where they are in the purchase process" (PHD, 2015).

Customer Service, Sales, and Relationship Management

The most recent and perhaps the most advanced applications of AI technology by marketers is evident in the areas of customer service, sales assistance, and relationship management. In May and August of 2015, Amazon and Facebook respectively introduced their AI enhanced customer assistance agents "Alexa" and "M." As described by one author, "buying items on Amazon would now be even easier than pressing a button with 'Amazon's Choice,' a new feature for the Internet-connected "Amazon Echo" speaker that will allow the unit to automatically order items in response to a voice command ... like Apple's Siri ... You "wake it up" with your buzzword, ask it to set reminders, play streaming music, and look up simple Internet queries (Beres, 2015).

Facebook's foray into the AI concierge market comes in the guise of "M." As described by Hackman (2015), M is

... powered by artificial intelligence, trained and supervised, and designed to help answer questions like 'Where is the best place to go hiking? Can you help me order flowers for my Mom's birthday?' Like Apple's Siri, Google Now, and Microsoft's

Cortana, Facebook's M "largely answers fact-based questions and performs simple tasks confined to a computing device. (Hackman, 2015)

Although, M goes

... a step further, making intelligent decisions on your behalf. As of now, however, Facebook is not tapping into its social graph to help answer those questions ... It's also not clear whether M will actually make a purchase for you, or simply point you to a service or website for you to take care of yourself. (Hackman, 2015)

Sophisticated AI applications in customer service have been developed by IBM. Envisioned as an intelligent technology whose services can apply to almost any industry, but especially those that receive many customer service inquiries, such as retailing, banking, insurance and telecommunications, IBM offers the Engagement Advisor (Lohr, 2013). IBM's Watson Engagement Advisor has the ability to scan, analyze, and interpret over 200 million pages of structured and unstructured data in a matter of seconds and subsequently enter into a natural language conversation based on its interpretation of and conclusions drawn from its analysis (Schiff, 2013). For any purchase the consumer is considering all that is needed is a quick query of Watson: Watson what is the best brand? What is the best price?

With the ability to analyze the personality of the consumers, categorize their lifestyle and buying style, extrapolate all their online information and communications, the marketer can now formulate the optimal marketing message for the right person at the right time and sell, cross-sell and up-sell their products.

FUTURE RESEARCH DIRECTIONS: THE FUTURE OF VIRTUAL ASSISTANTS

Sophisticated as current systems may be, the next generation of AI agents represent a paradigm shift

in AI marketing applications. Rooted in cognitive computing, advanced sensor technology, and natural language interfaces, the next iteration of the AI marketing agent is just beginning to emerge, and it fulfills the promise of that all-knowing and all-powerful entity that can obey and fulfill the consumer's ultimate command – "Tell me which brand is best to buy and why!"—transforming marketing.

Cognitive computing will be the ultimate marketing game changer, ushering in "the smart machine era" that (short of the singularity envisioned by Ray Kurzweil) "will be the most disruptive in the history of IT" (Austin, 2013). Today, Apple's Siri, Google Now, and Microsoft's Cortana are familiar companions to smartphone users. The consumer's unspoken thoughts are now being confirmed by the virtual personal assistant (VPA), which is designed to serve/guide them through everyday decisions. VPA's will soon be everywhere, and, yet, nowhere in the life of a consumer—a gateway to the Internet and other people like no other (Brauer, 2014). Already traces of its trajectory exist from mobile and wearable, to 'hearable' and perhaps one-day 'implantable' wearables, hearables, trackables, and even scent (Brauer, 2014). No doubt, consumers will initially want to determine when and where to synch their physiology, decision-making and emotions with a VPA, but, then real-time synchronization will just be easier and more efficient (Brauer, 2014).

In addition to knowing a consumer's tastes, needs, and desires, the VPA knows all past purchases, current preferences and future plans. Moreover, the VPA has a 360 degree view of the marketplace and can provide a ranking and recommendation of all competitive and comparative products. Rather than pushing a single brand, as a marketer's bot, the VPA more inclusively and objectively evaluates an entire evoked set of brands and proffers a recommendation aligned with and in the best interests of its master. Perhaps, in the long run the VPA will enable the consumer to gain the upper hand in the marketing game.

NEW RULES: NEW ROLES

As the marketer is increasingly disintermediated, it will become increasingly important for the marketing industry to recognize the primary role that the consumer's VPA plays in the marketing game and to adjust marketing efforts accordingly. Continuing to invoke the old moves in the new game will not only prove ineffective, but counterproductive in gaining consumers' trust and patronage.

However it remains that all too often one finds the application of AI agents has primarily served marketing professionals to augment and extend their traditional marketing toolset. It is fairly common practice to use data driven advertising, where click-through rate or revenue generated are used as a metric to identify which one of two ads is more effective (Ayres, 2008). Using AI techniques, ads are adjusted in real-time to make them more memorable or possibly more effective at converting views into revenue (Khosla, Bainbridge, Torralba, & Oliva, 2013). Google AdWords has advertisers bid against each other to auction space for ads on websites, based on the content of the page and the interests of the viewer, as reflected in the web cookies on his or her machine. Ostensibly, this leads to better, targeted ads. In the end, the consumer may not want fewer better, targeted, designed advertisements, but rather *no* advertisement.

Over the past decade, advertisements have become more and more intrusive. At one time, being selected to participate in a survey or a focus group made a person feel elite; however, today's consumer is constantly battling online ads (Arana, 2015). Such intrusion has spawned a variety of ad-blockers that attempt to alleviate users' frustration. Over the last year alone, ad-blockers in the United States jumped 48 percent – 16 percent of U.S. online users now try to block ads and 200 million people use ad-blocking software a month (Arana, 2015).

The claim is the rise of ad-blocking software is due to the increase use of mobile devices

when going online – smaller screen makes ads more intrusive. However, “not everyone in the ‘ecosystem’ users is inclined to see it that way” (Arana, 2015). Users are no longer receiving “‘sensible’ ads – generally defined as those limited to text or those appearing alongside, but not on top, of content” (Arana, 2015), which most are willing to support. Instead, most ads are intrusive, covering content, lacking a way to bypass them and blocking the user's screen for a fixed amount of time, up to tens of seconds in some cases. The reason for such an intrusive approach is the loss of focus of attention on user experience.

This increasing realization that the influence and impact of the marketer's commercial campaign is on the wane is further exacerbated by the fact that it may eventually be dismissed altogether when the consumer's purchase cycle is fully maintained and conducted by a consumer's VPA. As VPAs become available they will increasingly serve as the primary product purchasing platform for consumers. Accordingly, corporate marketers will need to address the VPA directly, instead, or in addition to the human target.

New Target: Market More to the Algorithm than the Consumer

In the emerging AI driven marketplace if you want to reach/influence the consumer you will need to reach/influence the algorithm that is controlling their communication stream. As argued in *Sentience: The coming AI revolution and the implications for marketing*, if one accepts “the likely scenario that our VPAs will be tasked with carrying out many of our day-to-day tasks, including searching for options,” then “it's clear it is our VPAs that will be making decisions on which brands/ products we should see... A significant focus for marketing will be to influence the algorithm and ensure that the VPA is surfacing your brands/ products ahead of your competitors (PHD, 2015).

New Rule: Access to the Consumer by Permission Only—Relevancy and Reputation Required

As the consumer's commercial gatekeeper, the AI agent will screen every attempt to enter its client's communication stream for relevancy and reputation. Relevancy may be determined by such factors as the time, location, expressed needs and established tastes. Reputation may be measured by both objective and subjective industry and consumer evaluations as well as the consumer's own past experiences. What product/service ultimately qualifies for consideration will be based on "extremely specific purchasing and behavioral data" unique to each individual. If the product/service meets the qualifying criteria it remains that an admission fee (or bid price) may be charged to the marketer for entry in/on to the communication stream.

VPAs will actually make the decisions on when to pull down a brand/product and surface-up a suggestion to their user... the bid price and relevancy/quality score are most likely to determine which brand, products or services are suggested... Then it will report back to the advertising company which ads were actually shown so that the company can bill its clients... All... will be handled in nanoseconds by our VPAs, and served up without us knowing which brands or products narrowly missed out. (PHD, 2015)

New Role: Reputation Management and Enhancement

Within this new paradigm of AI arbitrated commercial messaging a key variable that marketers must measure, monitor and bolster their company's or (for consultants) their client's reputation. Indeed, it has been suggested that managing a product/service's reputation is going to become a defining function of leading marketing practitioners. Marketers that can bolster the positive reviews and customer recommendations "will impact the

quality score, which in turn increases likelihood of the brand being selected by the VPA and/ or reduces the bid price required" (PHD, 2015).

New Role: AI as Utility

As another example of where the VPA technologies are currently, Viv Labs is a company that has recently announced a much more powerful agent than Siri, Cortana or M. Known as Viv, this AI agent will be able to quickly learn a user's preferences, and will be able to carry out complex tasks and answer complex queries for the user. The company founders view Viv as a utility, something that users can plug into and use whenever needed, as they use electricity. Viv will be a global brain, learning a user's preferences, but learning generic skills from its interaction with other users. This approach will allow the agent to learn much faster than a personal agent who interacts only with its own user. Users of Viv might be surprised to try something new, only to realize that Viv has already been trained to accomplish that type of task based on its interactions with other users. (Levy, 2014)

A side effect of AI as utility will arise from the ability of the global brain to aggregate feedback from countless interactions. Rather than relying on just a subset of customers to report experiences on Yelp or TripAdvisor, the Viv brain will automatically aggregate all the customer experiences and make that aggregate evaluation a part of any prospective transaction. This type of automatic and more objective reputation building for merchants will prevent some of the astroturfing techniques that currently involve the selective editing of reviews or providing incentives for some customers to post biased reviews.

New Rule: Toss Out the Rule Book

There is the old adage that marketer's "make people buy things they do not need, with money they do not have, to impress people they do not like." Regularly, traditional marketing relies on impulse buying (preference for a product that

is immediately available over one that is less available), cognitive heuristics and limitations (preference for a simple choice over a more complex choice), sensory overload (responding to appetizing smells or to arousing imagery) and irrational decision-making (including the inability to carry out complex calculations in one's head). In contrast, VPAs will be closer to the *homo economicus* ideal, with essentially unlimited ability to uncover and compare choices, with the ability to follow the user's preferences and not be swayed by the commercial message, and with the power to negotiate with several merchants at the same time. If consumers increase their reliance on VPAs, this will greatly reduce the success of some of the marketing techniques that rely on human traits. Marketers will need to truly understand what customers want, as well as how to reach those customer needs via the user's VPA. To summarize the new rules, marketers will need to market to the VPA algorithm (not to the user's human weaknesses). In marketing to the algorithm, marketers will need to gain the user's VPA's permission via reputation and relevancy. Finally, marketers will need to be aware of the AI as utility, and to realize that AI agents will communicate and share information, just as customers do today, just much faster and more comprehensively.

CONCLUSION

The role of AI in marketing is only in its nascent stage and its impact is predicted to increase exponentially. This entry illustrated applications in marketing that will impact both corporate marketing systems as well as those on the consumer's side. Research on corporate marketing systems will need to focus on how to use AI to improve current marketing processes. A related, but important research area will involve the customer perceptions of these AI systems. Because AI agents will learn about consumers' habits and will be able to infer behaviors, trends and preferences that might be

rather private, corporations will need to establish privacy policies that will reassure customers. Additionally, the rise of VPAs will have a considerable impact on how customers make purchasing decisions. As rational decision-making agents, VPAs will not be susceptible to the same types of marketing messages currently aimed at humans. Marketers will need to understand how to position their products and how to target a mixed audience of both humans and VPAs. Future research will also need to consider how VPAs will be created and deployed to gain the trust of consumers. Finally, a social concern is that the rise of VPAs will lead for further social inequalities. Wealthier people, who will be more likely to afford a more expensive and capable agent, will have even more access to the best deals (via the toughest negotiating agents), the most up-to-date information (via the most far reaching agent searches), and the most efficient consumption processes. Despite the possible economic benefits of VPAs, an unwise application of the technology has the potential to further deepen the digital divide, and to increase the inequalities that plague society. Further research will need to uncover ways in which such an outcome can be avoided.

Considering long-term implications, exploring the role of customer trust in the adoption of AI agents, the security requirements for agents, and the ethical implications of access to such agents this entry explored the new rules of marketing engagement. AI agents are upon us. The new roles—empowered consumer—are here and represented by AI, which is not so much a prediction, but a reality.

KEY TERMS AND DEFINITIONS

Artificial Intelligence: A computer system designed to exhibit features of human intelligence, including for example being able understand questions via natural language (human speech), solve

complex problems and present reasoning, and output answers using natural language.

IBM's Watson: Artificial intelligence system originally designed to showcase AI efforts at IBM by competing in the Jeopardy game. After winning Jeopardy in 2011 against the then-current champions, Watson was marketed by IBM for applications in medicine, customer service and general problem solving. Currently, Watson is being developed into a general purpose AI system that has been opened to a community of beta tester.

Intelligent Agent (IA): An artificial intelligence system, possibly endowed with human-like personality traits and with the ability to recall context and history of interactions in a manner that would facilitate future interactions with a human being.

Marketing Recommendation System (MRS): Computer system using AI or similar technology to make product, brand or feature

recommendations to customers. Some current systems have emerging abilities of this nature, but true AI systems are expected to provide insights much closer to those of expert sales staff.

Siri: Apple's personal assistant on the iPhone/iPad/iPod platform, able to understand and respond to basic questions using natural language using AI in the cloud. While Siri was one of the first AI agents in general use, its capabilities are rudimentary compared with those expected of true AI systems.

Virtual Personal Agent (VPA): Intelligent agent that is intended to assist a human user with purchases over time, developing a relationship and a context that optimizes the communication with the human user; for example, the VPA could remember the preferences of the human user and would be able to reorder items from a favorite brand or to suggest brands that would best meet.

Marketing and Marketing Plan for Information Services

M

Sérgio Maravilhas
Universidade Salvador, Brazil

INTRODUCTION

Marketing is a social and economic process through which individuals and groups meet their needs¹ and desires² by creating and exchanging products³ (and services) among themselves (Kotler, 2000).

Initially, marketing was practiced by companies in selling sectors of products and services and did not seem to fit the non commercial side. However, in recent decades almost all types of organizations adopted the methods and practices of marketing (Iacobucci, 2001), including information services.

To carry out a coherent program of dissemination of products / services developed by an organization, it is necessary to develop a program to properly plan all the actions and resources needed to achieve these objectives, and effectively control the deviations relative to them, allowing correcting the actions that do not get the expected results in order to constantly improve the system implemented (Mohr, J., Sengupta, S., & Slater, S., 2010).

For this it is necessary to devise a marketing plan that focuses on the planning of all activities and objectives we want to achieve and the means necessary to do so (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000).

The Marketing Plan is a strategic document that will serve to identify the position occupied in the market⁴, set goals and how they will be achieved, all the resources that are needed and expected results.

The purpose of this plan is to enable entrepreneurs to capitalize its resources, spreading the information on the goods and services they provide and channeling the profits derived from such use for their own funding.

BACKGROUND

According to Kotler (2001), Marketing is a social and economic process through which individuals and groups meet their needs and desires by creating and exchanging products (and services) among themselves.

We must consider that marketing has to do with the satisfaction of needs and that if several economic, technological and human efforts are made in order to satisfy those needs, ultimately, society as a whole will be the one who benefits the most (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000).

Initially, marketing was practiced by companies in sectors of products and services selling and did not seem to fit the organizations with non commercial side, like information services, with no intention of making a profit. However, in recent decades almost all types of organizations adopted the methods and practices of marketing. Examples of this practice are political parties, religious bodies, social, philanthropic and charitable entities, in a logic which was instituted to be designated as Social Marketing (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000).

The adherence to this practice of management should have in mind the services providing information, essential for the development of collaborative R&D and innovation, although not strictly commercially oriented and intended to make a profit through the products and services they provide (Batchelor, 1997).

Let us not forget that, according to Kotler (2004, p. 9)

The fact that most of these services are 'free' does not affect the characterization of the products. A product is something that has value to someone. Charge or not for your consumption is a trait tangential, unessential, the definition of its value. In fact, most of these social goods has its 'price', although this is stated not in the usual way.

Thus, by referring to nonprofit suppliers of this type of product and service we cannot talk about companies but organizations, nor speak of customers but publics. Rather than speak of sales we should be promoting behaviors and instead of return we should mention the achievement of objectives.

Knowing that the objectives can be non-financial, in this perspective we should opt for a broader definition: «Marketing is the set of methods and means that an organization has to promote the behaviors, conducive to the realization of their own objectives, in the public's that interest them. (Lindon et al., 2000, p. 30)

We will not discuss here if Marketing satisfies or creates needs because, in one way or another, in the end it will be a need (created or not) that will be satisfied.

According to Zachert and Williams (1986, p. 61) the basic idea of marketing is that the effective response to the needs and requirements of customers are the key to the company's success in the market, being the most successful organization the one that has a proactive attitude towards the constant challenges faced by their clients.

To know our market, and customer requirements contained therein, it's necessary to obtain relevant information about consumer habits and behaviors. We can therefore say that the need to obtain relevant information exists in every business. Seems that companies, especially small ones (which constitute the majority of businesses) have this latent need, but are not informed about what information will meet their needs.

Someone must take the initiative to help them, informing them and directing them to ways of obtaining and using the resources of information from various sources, in order to enable the best way to meet the needs identified in their publics and markets where the company operates.

Also according to Zachert and Williams (1986, p. 61) the organization must foster participation of its customers to allow the design and development of products and services that fit their needs and requirements. The secret, they say, lies in a personal and open communication with them.

MARKETING-MIX: THE FOUR 'P'S'

Although the commercialization plan, or Marketing-mix, encompasses many activities, in the early 60's Jerome McCarthy proposed a four 'Ps' Marketing-Mix.

These four 'P's' are:

1. Product;
2. Price;
3. Place;
4. Promotion.

They define what is the product/service that our publics really want, the price they are available to pay to have it, where and how can they find and buy it the way they prefer to do it, and how can we communicate with our publics, by which means and media, to let them know we have what they want (Walker Jr., O., Mullins, J., & Larreche, J.-C., 2008).

The framework of the four 'P's' demands (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000):

1. That the people in charge of marketing decide about the product / service and its characteristics;
2. Establish the price;
3. Decide how best to distribute the product;
4. Choose methods of promoting it.

According to Kotler (2001), at least two more 'Ps' should be included, which are extremely important in the global market: Politics and Public. For Kotler, this marketing mix is the set of controllable variables and their levels, which the company uses to create a defined positioning in the environment and to exert an influence on the market that it targets.

These four Marketing variables must direct to and fit our market because a good marketing strategy involves these marketing mix variables perfectly tuned with the fixed target market of our business. But for that to happen, it is imperative to know who our targets are. Therefore, knowing the market implies classify it, segment it, investigate it, to know the consumer and how he decides the process of obtaining goods and services, how often, and so forth.

MARKET SEGMENTATION

We know a market when we can answer the following questions (Iacobucci & Calder, 2003):

1. Who are our potential clients/publics?
2. What do they buy (in terms of products or services)?
3. When do they buy?
4. Who is involved in these purchases?
5. Why do they buy these products or services?
6. How do they buy?

Answering these questions allows us to differentiate the market where we intend to act.

Thus, the strategy should be directed to the segmentation of the market, which means rank the total market of a product or service in a number of homogeneous subsets such as the habits, needs and tastes of its components, calling up each of these subsets as a market segment (Walker Jr., Mullins, & Larreche, 2008, p. 133). Simply stated, the intention of segmentation strategy is to meet the needs of a customer group with appropriate products and services. "Market segmentation is the process of identifying distinct groups of buyers who might require separate products and/or marketing mixes, then creating a profile of each group" (Rea & Kerzner, 1997, p. 41).

The purpose of identifying these segments is to enable companies to better tailor their Marketing policies to all or some of these subsets.

Segmentation is a strategy that aims to address not the public as a whole, but the different groups in more specialized ways.

The three most important steps in the market segmentation process are:

1. Identify a homogeneous segment that differs from other segments;
2. Specify criteria that define the segment;
3. Determine segment size and potential (Walker Jr. et al., 2008, p. 133).

Kotler (2000, pp. 263 - 269) describes some bases, or variables, of segmentation:

1. **Geographic:** Dividing the market into different geographical units such as nations, states, regions, counties, cities, or neighborhoods;
2. **Demographic:** Dividing the market into groups on the basis of variables such as age, family size, family life cycle, gender, income, occupation, education, race, religion, generation, nationality, and social class;
3. **Psychographic:** Buyers are divided into different groups on the basis of lifestyle, personality, and values;
4. **Behavioral:** Buyers are divided into groups based on their knowledge of, attitude toward, use of, or response to product characteristics.

For these variables to work effectively we must combine them in order to identify smaller and better defined target groups.

The benefits of segmentation are (Walker Jr. et al., 2008, p. 133):

1. Recognizing the importance of each segment;
2. Detecting and analyzing opportunities offered by the market, assessing the degree to which the needs of each segment are covered by existing products or services;
3. Tailoring products and marketing policies to the tastes, needs and preferences of each segment;
4. Defining strategies and budgets based on the most reliable information for each specific segment and make sales predictions safer and sounder;
5. Allowing adaptation of advertising and media related to the characteristics and habits of each segment;

Organizing the best way to deliver the product / service to potential buyers, according to the consumption characteristics of each segment.

Depending on the segmentation performed, there are three possible strategies:

1. **Undifferentiated Strategy:** The same for all segments. Means lower costs but in return there is less adaptation to markets;
2. **Differentiated Strategy:** Different strategies and products for each market segment. The offer is best suited to the segments allowing better results. May involve higher costs but allows better achievement of the proposed objectives;
3. **Focused Strategy:** To focus on a particular sector, facilitating a better understanding of the target customers and hence greater loyalty and participation, even if the focus is on a more limited market.

Marketing strategies are based on market segmentation, meaning that the majority of products

and services do not address the entire market but specific groups of consumers.

The choice of the strategy will depend on several factors (Jobber & Ellis-Chadwick, 2013):

1. Resources available to the organization;
2. The characteristics of the product or service;
3. The product life cycle;
4. The homogeneity of the market.

Besides all these constraints to adopt a strategy, a policy of targeting can bring significant advantages.

If it is certain that all alternatives may have their exceptions sometimes affront the installed habit can assume a competitive advantage.

Segmenting (S) the market is the first step, targeting (T) the segment that we want to work with is the second. The third step is positioning (P), making STP a powerful tool in the marketer toolbox.

POSITIONING

This refers to the set of images through which the market 'sees' a company, product, person, or even an idea, and clearly identifies it (even among similar ones).

Positioning is one of the Marketing action lines more attractive, complex and key success factor in current competitive dynamics. It is normal to develop around the product or service and divide itself between repositioning of existing products or services and positioning of new products or services.

Positioning is the set of the salient and distinctive image that allow the public to place the product on the universe of similar products and distinguish it from others. In other words, it is a representation (or perception) simplified, reductive, comparative, and distinctive of the product. (Lindon et al., 2000, p. 139)

Positioning, for a permanent activation of the competitive dynamics, involves:

1. The competence, courtesy and credibility of people in contact with customers;
2. The written and visual forms, the work environment, and the symbols used;
3. The 'service' relation with the customers;
4. Interaction, features, style, design of products / services, with the foregoing;
5. The planned, organized, controlled way, but at the same time flexible and creative that each company chooses to act in the market.

In consumers' minds must prevail the 'name' of the company or brand, so distinct and unique to be remembered whenever the consumer needs to acquire the same type of goods or services. By establishing a preference for quality and satisfaction in previous acquisitions, it must become pronounced in his mind.

MARKETING AND COMPETITIVE ADVANTAGE

The organization should learn how to detect needs and adopt a proactive stance in relation to those who can assist in satisfying their needs (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000).

We cannot be waiting for them to seek us, because for various reasons this may never happen (Walker Jr., O., Mullins, J., & Larreche, J.-C., 2008).

It is imperative that we send information about our product line to the interested publics and, if it becomes necessary, a technical explanation to accompany it for companies less endowed in terms of intellectual capital⁵ so they can seize it and draw the appropriate lessons that enable them to design products or perform services able to provide them with competitive advantages (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013).

Consequently, the increase of more specialized and specific product development, for example, with more customized services (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000).

This idea of joining product with service gives rise to the notion of expanded product which is a form of differentiation of a product with value added that allows obtaining competitive advantages (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000).

The main sources of market opportunities are (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000):

1. Provide a scarce article not widely available;
2. Provide articles or existing services in a new or better way;
3. Provide a new product or service.

So, Marketing applied to improvements in the satisfaction of needs and desires can actually lead to a way of generating competitive advantage for businesses and, by doing that, improving the wellbeing of the society.

MARKETING PLAN

To be able to carry out a coherent program of dissemination of products / services sold by us, it is necessary to develop a program to properly plan all the actions and resources needed to achieve these objectives, and effectively control the deviations relative to them, allowing to correct the actions that do not get the expected results in order to constantly improve the system implemented (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000).

For this it is necessary to devise a marketing plan that focuses on the planning of all activities and objectives we want to achieve and the means necessary to do so⁶.

Let us not forget that "To fail to plan, is to plan to fail".

The strategy outlined here should last 3-5 years (Walker Jr. et al., 2008, p. 133). However, its evaluation (and, if necessary, reorganization) should be done annually.

In order to properly define the alternatives to follow, the steps for the preparation of the Plan are:

1. **Analysis of the Market (Commercial Research):** By which we collect and gather all the information needed to make decisions and to select alternatives, like for example:
 - a. Who will be our market (who are our customers - or publics -, their needs, motivations, etc.);
 - b. How to deliver the product or service (best way to distribute the product / service for our customers: specialty stores, Internet, large retail, etc.);
 - c. The price to pay for the product / service (payment forms more suitable for our customers, importance of price in obtaining the product or service, etc.);
 - d. Demographic data (number of customers in a given market, qualifications, salary, areas of interest, family life cycle, etc.);
 - e. Communication (best way to reach our service to potential stakeholders: Media, Newsletters, Social Media, etc.).
2. **Commercial Planning:** In relation to the process of marketing this will be the basis of its development and must be done according to the selection of commercial alternatives and information we've collected in point 1. It is here that the alternatives to adopt will be developed, planned and executed, and must specify the resources necessary for its effective realization (financial, human and material), as well as its temporal variable that must be annual but must take into account the strategy of the organization in the long term (3-5 years).
3. **Business Organization:** To plan for the work is not just its preparation but people

are also needed, appropriate to the function, to execute it. Also important is the organizational system to implement so the plan can work (customer service, administrative support, technical support, etc.).

4. **Commercial Control:** The Marketing Plan should have its objectives well developed and quantified so they can be monitored during its operation. This allows knowing if the objectives are being met and if adjustments need to be taken to improve it (Lindon, Lendrevie, Rodrigues, & Dionísio, 2000).

The marketing plan is a strategic document that will serve to identify the position occupied in the market, set goals and how they will be achieved, the resources that are needed and the expected results.

Being this plan a part of the organization Business Plan, its implementation should be proposed at the highest level (the Board) to be accepted without reservation by all stakeholders (Donnelly, Gibson, & Ivancevich, 2000; Rea, & Kerzner, 1997).

The purpose of the preparation of this Plan is to enable entrepreneurs to capitalize on its resources, spreading the information on the goods and services they provide and channeling the profits derived from such use for their own funding. At the same time, aims to allow increased competitiveness and economic growth to companies that use the information collected for the preparation of this Plan, enhancing competitive advantages.

If we think of a plan as the definition of what an organization hopes to achieve, how and when, and the act of planning as a systematic way of an organization seeking to control the future, we deduce easily that the planning benefits are:

1. Promote a systematic reflection about the future;
2. Enable a better coordination of the resources;
3. Establish performance goals, allowing to measure results;
4. Provide a rationale for decision making;

5. Improve the ability to face changes;
6. Promote the ability to identify market opportunities (adapted from Kerin et al., 2006).

FUTURE RESEARCH DIRECTIONS

Further research should be conducted to evaluate the benefits of introducing these concepts in the daily work of information services, in order to extract best practices that could be applied where needed. Using benchmarking, it is possible to improve what's not working and benefit from others experience and expertise, improving results.

CONCLUSION

Marketing activity is one of the most important management activities of modern societies (Dibb et al., 2006; Jobber & Ellis-Chadwick, 2013; Kerin et al., 2006; Kotler, 2000). To be able to satisfy consumer's needs and desires better than their competitors, product quality, extraordinary service and customer support are needed, giving customers and the society in general the best that is possible with the means at their disposition (Iacobucci, 2001).

With the advent of Internet and mobile technologies (Michael & Salter, 2006), supported by Social Media and Web 2.0 tools (Ryan & Jones, 2012), new marketing strategies are being shaped to adapt to these new media and its users (Iacobucci & Calder, 2003). Digital marketing, social media marketing, web marketing and other similar concepts are taking shape (Ryan & Jones, 2013). Nevertheless, although the technologies and digital platforms are evolving, making some of the work easier but making some parts even difficult, the basics of Marketing are the same: users needs and desires, segmentation, targeting, positioning, product, price, promotion and distribution (Ryan, D., & Jones, C., 2012, 2013) are always needed to perform, but now they are supported by new ways

of interacting with the company publics (Jobber, D., & Ellis-Chadwick, F., 2013).

Every company – new or already in the market – needs a marketing plan, included in their annual business plan (Donnelly et al., 2000). A start-up needs a marketing plan to attract investors and other shareholders and stakeholders. Companies already operating need it for the same reasons, but also to 'keep an eye on the shore' and not let competition get ahead with an advantage knowing always where they are heading and where they want to get in a certain period of time (Rea & Kerzner, 1997).

We hope to have contributed to a better understanding of what marketing is and what are the characteristics and advantages of developing a marketing plan for establishing a strategy to be followed by the company in order to achieve its objectives.

The marketing plan should not be seen as a static document, unaltered, but as a dynamic element that can and should be adapted and adjusted according to changes that may be detected in the markets in which the company develops its activity. The marketing plan should be seen as a road map.

This does not require us to follow any specific path, but it helps us to see what the best way to achieve our goals is. In case of a blockage in the first route, it easily allows us to adjust the path and set a new route.

KEY TERMS AND DEFINITIONS

Competitors: A company in the same business or similar industry which offers a similar product or service. Competitors can lower the prices of products and services and gain a larger market share, reducing clients and lowering profits.

Market: The set of offers and searches for a product or service in a particular sector. It's the place where offer and demand get together.

Marketing Plan: A strategic document that will serve to identify the position occupied in the market, set goals and how they will be achieved, all the resources that are needed and expected results. The purpose of this Plan is to enable entrepreneurs to capitalize its resources, spreading the information on the goods and services they provide and channeling the profits derived from such use for their own funding.

Marketing: A social and economic process through which individuals and groups meet their needs and desires by creating and exchanging products and services among themselves. Nowadays, is one of the Marketing action lines more attractive, complex and key success factor in current competitive dynamics.

Positioning: Relates to the set of images through which the market and its customers 'sees' a company, product, person, or even an idea, and clearly identifies it, even among similar ones.

Segmentation: The process of identifying distinct groups of buyers who might require separate products and/or marketing mixes, then creating a profile of each group. Divide the total market of a product or service in a number of homogeneous subsets such as the habits, needs and tastes of its components, calling up each of these subsets as a market segment.

Strategy: The way an organization chooses to do his business in order to surpass competition and gain consumers preference. What is going to do, how, for whom, using what resources, and so forth. It's the plan to conduct business, maximize profits, allocate the needed resources, and stay in the market as long as possible. Includes foresee

what can happen, using forecasting methodologies and tools, in order to avoid problems or, if they happen, be prepared to minimize their effects.

ENDNOTES

- ¹ “The notion of need translates the attitude of the potential consumer that is waiting or looking for anything; this state of frustration will only be overcome with the possibility of (...) having the desired good or service” (Machuret, Deloche, & D’Amart, 1996, p. 39)
- ² Desire can be described as the outward expression of need or personal will to satisfy a need (Donnelly, Gibson, & Ivancevich, 2000)
- ³ The product is the good or service that meets one or more requirements to satisfy

the necessity or desire (Dibb, Simkin, Pride, & Ferrell, 2006; Jobber & Ellis-Chadwick, 2013; Kerin, Hartley, Berkowitz, & Rudelius, 2006; Kotler, Wong, Saunders, & Armstrong, 2005; Lindon, Lendrevie, Rodrigues, & Dionísio, 2000)

- ⁴ “The market is defined as the set of offers and searches for a product or service in a particular sector” (Machuret et al., 1996, p. 39)
- ⁵ “Intellectual Capital - refers to the capacity, skill, experience and also the formal knowledge of people working in the company” (Silva & Neves, 2003, p. 407)
- ⁶ According to Batchelor (1997, p. 373) there are three stages when performing the iterative marketing goods or services: “These stages are marketing strategy, service delivery and implementation of the marketing plan”.

A Neuroaesthetic Approach to the Search of Beauty From the Consumer's Perspective

M

Gemma García Ferrer
Rey Juan Carlos University, Spain

INTRODUCTION

Consumers pursue hedonism and beauty throughout the decision-making processes regarding purchases and consumption. Even though rationality and functionality are part of these processes, the role of emotions is also evident. The five senses (sensory marketing) will be essential in the aesthetic perception that consumers have in these processes.

Therefore, consumers will go to points of purchase which they consider attractive, such as emblematic shopping streets, shopping malls with magnificent architecture, well-decorated and well-furnished designer brand stores, window displays which show the most important features of a store without being necessary to go inside it, well-lit and tidy supermarkets and so on.

Consumers want the packaging of the products to satisfy their needs of making a gift to other people or to themselves. They also want the color combination to be attractive and to boost their mood or the mood of the person who they would like to please.

The product needs to be visually appealing—we can even think of something as simple as a piece of fruit, or something much more sophisticated, such as a cellular phone.

Advertising strategies (billboards, commercials...) need to stimulate this quest for beauty.

Marketing strategists have been aware of this reality for a long time. However, the new neuromarketing and neuroaesthetic techniques can be useful complements to understand the consumers' quest for beauty.

The objectives of this article are to analyze the aforementioned consumers' quest for beauty, by specifying neuromarketing's possibilities and techniques, and to define the concept of neuroaesthetics and its usefulness.

BACKGROUND

A good starting point is the research carried out by Wang, Cruthirds, Axxin & Guo, C. (2013) about the essential value of aesthetics in consumer marketing. According to these authors, there has been disagreement among scholars regarding this aspect throughout the years. Nevertheless, this concept is completely accepted nowadays.

Strategic marketing and specific actions on marketing variables are heading in this direction.

As a useful tool to obtain information throughout the marketing process (Ferrer G.G., 2012), market research uses conventional or non-conventional (more innovative) techniques to increase the aesthetic value of the items to be offered to the consumer.

Consumers will appreciate beauty and aesthetics from the moment when the purchasing process begins. Everything will be sensorial stimuli which consumers perceive in a unique and different way. The five senses will become essential and a company's success will depend, to a great extent, on the fact that the individual's sensory sensations are satisfactory.

The product and everything that surrounds it should be aesthetic and beautiful in the eyes of the consumers. Throughout the chapter, the value

of aesthetics in the point of purchase, packaging, advertising strategy and in the product itself will be analyzed.

As we will see throughout the chapter, non-conventional market research about neuromarketing and neuroaesthetics will obtain physiological and biological measurements as a sign of the individuals' feelings: how they perceive advertising, billboards, promotions, packaging, brands, the place of purchase or the product itself.

MAIN FOCUS OF THE ARTICLE

Aesthetics in the Points of Purchase

Concerning the purchase of convenience products, it is usual that consumers look for a good price. However, this is not the only factor that has an influence on the products' purchase. In fact, we can list several aspects which are directly related to a delightful aesthetic combination, such as lighting, well-organized corridors and shelves and a rich combination of smells (Aldana, Serpa, Ortega & Ochoa, 2010). These factors also apply to online shopping, as it should not only be user-friendly and reliable, but also visually appealing.

Something similar will happen with the purchase of products which are not frequently needed by consumers but are more related to personal feelings of self-satisfaction. Consumers will not only see all their wishes fulfilled with the product itself. As a matter of fact, their emotions (quests for pleasure and wish fulfillment) will expand to the act of "going shopping". Such act will be accompanied by a wide range of sensory stimuli offered by the point of purchase (music, smells, possibility of seeing and touching the product, enjoying a specific atmosphere, interacting with the salesperson...) Walking along a shopping street means coming into contact with the landmarks of a city. This does not only satisfy the consumers' wishes to purchase something, but it brings those consumers closer to the world of architecture,

culture, history and art. For this reason, sensory stimuli are not only produced by the business establishment.

The physical marketing channel plays a fundamental role in the consumption and purchasing experience, and it enables consumers to come into contact with the real atmosphere of the brand.

The most important brands have their own stores and extend the concept of brand to the business establishment itself. In this regard, single-brand stores will take special care of the brand image, and this will show in aspects such as window displays, decoration, furniture and the product arrangement.

The concept of flagship store constitutes a usual and powerful tool of communication, which is supported by geomarketing studies. Flagship stores are located in landmarks of big cities, as well as in heavy pedestrian traffic areas, popular with both city residents and tourists. These stores represent the cutting edge of innovation and creative design. The term "flagship" comes from nautical terminology and was used for the first time in the world of fashion to define stores "which can wave the flag with the brand image". These shops' area ranges between 1,500 and 2,000 square meters (approximately 16,000-21,000 square feet) and their architecture brings the observer closer to the world of culture, art and glamour, as flagship stores are often located in renovated and refurbished historical buildings. Their interior displays tasteful decoration, the latest (and some of the past) fashion collections and advanced technologies such as interactive presentations with augmented reality. Other types of services, which increase the experiential and hedonic value in the purchasing process, are offered in these stores. Such services include private areas, spas, art galleries, cafeterias or restaurants, live music, exhibitions, fashion shows, talks and tasting sessions, among other possibilities.

Pop up stores (Lassus & Freire, 2014) are ephemeral nature stores which open for a short period of time and which also belong to the luxury

market. Pop up stores are more than simple stores: they are also a show, something special and extravagant. Thanks to them, the brand image can be transmitted with a minimum investment risk and low costs. Their temporary locations are usually placed in city landmarks, aiming at large turnouts of people.

Regarding virtual stores of products which are not frequently purchased, the aesthetic combination is also extremely important.

Aesthetics in Packaging

Product packaging does not only play the roles of containing and protecting the product, being functional and looking for constant innovation. As a matter of fact, it is also part of the product design and it is a key element in its sale. Furthermore, we need to take into account the high-level competition in all sectors of the market (Stalman, 2005). The packaging and its careful handling is essential, not only because of the information that it must contain, but also because of the message shown in it, its shape and its colors, which need to arouse hedonic values and emotions.

There are different types of packaging: those of simple products like bottles of water, which need to transmit purity, or those which are more sophisticated, such as perfumes or cosmetic products. In the latter, consumers' aspirations are more related to improving their self-concept and are closely connected to personality.

With this more sophisticated type of packaging, consumers aim at making a gift to other people or to themselves. Therefore, wishes and illusions skyrocket and aesthetics becomes much more important (Martín & Martín, 2012). We just need to think about the gifts we buy for key occasions like Christmas or St. Valentine's Day.

One of the aspects which have a greatest influence on packaging aesthetics is color and its psychological implications. The effects of colors on the consumer are summarized below:

1. **White:** Together with black, it is located on the extreme point of the grey range. White can convey peace, happiness, activity, purity and innocence. White is the universal background of graphic communication.
2. **Black:** It symbolizes silence, mystery and sometimes certain malignity. It confers nobility and elegance, especially when it is bright.
3. **Grey:** It is neutral and passive. It symbolizes indecisiveness and lack of energy. It can also convey doubt and melancholy.
4. **White and Black:** Along with gold and silver, are the colors of prestige. Red or purple can have a similar effect.
5. **Yellow:** It is the brightest, warmest, the most blazing and expansive color. It is also lively, cheerful, exciting, emotional and impulsive. In addition, it is related to nature.
6. **Orange:** It has a cozy, warm, stimulating character and very positive and energetic dynamic qualities.
7. **Red:** It conveys vitality. It is the color of blood and passion. It expresses sensuality, and is the symbol of burning and overflowing passion, sexuality and eroticism.
8. **Blue:** It is part of the cool colors. It conveys harmony, friendship, loyalty, calm and serenity. This color is associated with the sky, the sea and the air. Light blue can suggest optimism.
9. **Violet (Mix of Red and Blue):** It is the color of lucidity and reflection. It is mystical and melancholic, and it could also represent introversion. When it gets closer to purple, it projects a feeling of majesty.
10. **Green:** It is the calmest and the most sedating color. It brings to mind vegetation, freshness and nature. It is associated with hope. It is reminiscent of the fall atmosphere.

Each packaging color can cause a different reaction.

Aesthetics in the Product Itself

Our introduction pointed out that the quest for aesthetics or beauty in a product occurred with items as simple as a piece of fruit. For example, consumers argue that one of the disadvantages of ecological products is their less attractive appearance. However, aesthetics is also sought with more sophisticated products, such as computers or cellular phones.

Furthermore, product design needs to trigger experiences, to please the consumer and to stimulate the five senses: taste, sound, smell, touch and sight. This is sensory marketing, which will act in one way or another, depending on the type of product (Abril, Avello & Manzano, 2011; Krishna & Schwarz, 2014).

When we purchase a product, our intention is to increase our happiness, improve our self-concept and make other people have a superb impression of ourselves. Beauty is pursued in all aspects surrounding the individual and everything that we purchase: furniture, clothing, technology, convenience products and so on.

Just as with packaging, shape and color also contribute to aesthetics (Blijlevens, Carbon, Mugge & Schoormans, 2012).

Aesthetics in Advertising Strategy

The way of making the product known, either in the point of purchase, as we have previously mentioned, or via conventional advertising, has to contribute to the beauty perception of the consumer.

There are simple examples which show this concept, perhaps to a greater extent in the case of advertising aimed at women, as they are more concerned about reinforcing their own self-concept: perfumes, cosmetic products, clothes and accessories.

Anyhow, a billboard or a commercial should appeal to beauty and be attractive for the consumer. As we shall see later, neuroaesthetics has been

applied in the cinema industry and in the same way, it can be applied to advertising.

Advertising is an everyday phenomenon, which obviously has, among others, the function of fostering consumption. However, advertising should also be understood as an art –we seek in it seduction, fantasy, and ultimately, creativity. On the one hand, it is extremely criticized, but on the other hand, it stays in the viewer's retina (González Valerio, 2007).

Neuromarketing, Its Techniques and Its Usefulness in the Understanding of Beauty Assessment by the Consumer

Conventional market research techniques (Malhotra, 2008) do not manage to understand the significance of the consumer's behavior. For this reason, further procedures belonging to neuroscience have been used for several years. Such procedures are known as neuromarketing. Among other authors we can mention the following: Al Pop & Iorga (2012); Braeutigam (2005); Braidot (2009); Hammou, Galib & Melloul (2013); Nakagawa, T. (2011); Senior, C. & Rippon, G. (2007); Stewart & Furse (1982).

Neuroscience and Marketing converge into Neuromarketing, whose scope is multidisciplinary: Economics, Marketing, Sociology, Anthropology and Psychology. Neuromarketing revolutionizes Market Research and its applications to the whole Marketing process (analytical marketing, strategic marketing and operational marketing). It enables managers to take decisions related to their product or service in a very effective way. It is applied by doing neurological, physiological and biological tests to individuals. Therefore, it is much more difficult that such individuals lie, like in conventional market research. These tests are normally done in a laboratory. Next, some of these procedures will be listed:

- **Eye Tracking:** It can measure eye movements of an individual and track their point

of gaze (Duchowski, 2002, 2007). It has several applications: visualization of an advertisement or a website (usability studies) or eye gaze tracking analysis in a supermarket shelf.

- **Pupilometer:** It measures the variations of the pupil diameter as a response to a stimulus, such as advertising. Eye Tracking and Pupilometer techniques can be used together. There are laboratories that combine the use of both approaches (Carbon, Hutzler & Minge, 2006).
- **Psychogalvanometer:** It measures sweat variations, also as a response to a stimulus.
- **Voice-Pitch Analysis:** It enables us to assess emotions, which is very important in marketing.
- Analysis of individuals' saliva when they are looking at images (Sánchez-Navarro, Maldonado, Martínez-Selva, Enguix & Ortiz, 2012).
- **Evoked Potential:** Electrical response of the brain to a sensory stimulus.
- Heart rate.
- **Facial Electromyography:** Movement of facial muscles.
- Eye blinking.
- Skin conductance.
- **Functional Magnetic Resonance Imaging (fMRI):** It is a functional neuroimaging procedure that shows images of brain areas which perform certain tasks.

There is an increasing number of multinationals which hire the services of companies and laboratories specialized in Neuromarketing.

This list gives us an idea of the possibilities of neuromarketing and the ethical debate around it. It is understood that there is a need for updated codes of ethics which regulate the use of these procedures, as well as their use along with conventional research methods (Murphy, E. R., Illes, J., & Reiner, P. B., 2008). What is evident is that any of the aforementioned procedures can

help us to get to know the consumer's appreciation of beauty.

Neuroaesthetics and its Usefulness in Understanding the Consumer's Appreciation of Beauty

One of the disciplines belonging to neuroscience is neuroaesthetics or neurobiology of beauty. It arises from the convergence between neuroscience, aesthetics and creativity and is supported by psychobiology. It can be applied to all kinds of art: painting, sculpture, music, dance, cinema... Neuroaesthetics (normally) measures how individuals perceive beauty by means of brain responses. For this reason, it can also measure how the consumer perceives the creative aspects of the marketing strategy. All the creative arts can benefit from this new science and in fact, marketing is one of them: luxury products, conventional products, billboards, commercials...

Semir Zeki is the pioneer of neuroaesthetics. In his research he measured several individuals' neural responses to different stimuli such as paintings or photographs, analyzing the increasing areas of the neural activity in regard to beauty perception (Kawabata and Zeki, 2004). According to Semir Zeki (2009), creativity is determined by the attempt to satisfy the dissatisfied brain concept. Permanent dissatisfaction is one of the most powerful ingredients for creativity.

Neuroaesthetics has even been taken to film analysis (Andreu Sánchez & Martín Pascual, 2011) and as we mentioned before, it can be applied to the field of advertising.

SOLUTIONS AND RECOMMENDATIONS

Consumers pursue pleasure, emotions, beauty and aesthetics in their decisions of purchase and consumption, starting from the moment when they check a website or when they decide to go to a shopping street or mall.

All the marketing strategy needs to head in this direction. Consumers fill up their existential emptiness with their purchases and pursue positive perceptions that make them feel better.

Sensory marketing aims at the consumers' five senses and facilitates this quest for beauty.

In order to analyze marketing strategies and their results, we can use not only conventional research techniques, but also neuroscience techniques (neuromarketing and neuroaesthetics).

FUTURE RESEARCH DIRECTIONS

Future research aims at improving consumers' aesthetic perception. Understanding the individual's physiological and brain mechanism as a response to stimuli is a key element in the success of marketing strategies.

Multidisciplinary studies –in this case, we can see the contribution of psychobiology- play an essential role in the understanding of individuals and their perception processes. Along with other science disciplines and with more conventional techniques belonging to them, it is considered relevant to analyze the impact of beauty on consumption and purchasing mechanisms.

CONCLUSION

Neuroscience disciplines (neuromarketing and neuroaesthetics) are key to understand physiological and brain mechanisms on how consumers process creativity in the case of marketing.

It can be stated that consumers pursue beauty throughout the whole purchasing and consumption process.

In the purchasing process, the consumer will appreciate and perceive the beauty of a marketing strategy through the five senses. Non-conventional techniques of neuromarketing and neuroaesthetics can turn out to be very efficient complements to

conventional research, since they are based on biological and physiological data.

Creativity and aesthetics are fundamental values which should be sought by marketing strategists and managers.

KEY TERMS AND DEFINITIONS

Beauty: It is understood as something that gives pleasure and satisfaction to the consumer from the aesthetic point of view.

Creativity: Basis for art, originality and imagination.

Neuroaesthetics: Measurement of the neural response of an individual to beauty.

Neuromarketing: Application of neuroscience and its methods to marketing and in particular, to the study of emotions.

Psychobiology: Branch of psychology which measures biological and physiological responses of an individual.

Sensory Marketing: Use of the five senses to capture the attention of the consumer.

Strategic Marketing: Planning of the segmentation and positioning in the consumer's mind, in order to determine afterwards the marketing mix in the short term.

Social Media Use and Customer Engagement

INTRODUCTION

Social Media has revolutionized customer relationships; opening a new array of possibilities and opportunities for firms. Social media tools are fundamentally changing the way we communicate, collaborate, consume, and create; and they represent one of the most transformative impacts of information technology on business (Aral et al., 2013). Platforms such as Facebook, Twitter, YouTube, Instagram, Pinterest, have millions of daily users and are said to capture the “wisdom of the crowd” (Luo et al., 2013). So firms all over the world are increasingly using these tools, integrating them into their communication strategies to engage customers in active conversations. In this new 2.0 environment, traditional Customer Relationship Management (CRM) strategies are morphing to Social CRM. The latest trend in CRM is to try to take advantage of Social Media, whose relational properties and characteristics are particularly suited to customer interactions (Harrigan et al., 2015). Social Media is all about engagement and collaboration. The proliferation of these platforms has changed the way firms communicate with customers, driving companies to implement a new variety of Customer Engagement strategies. New media offers companies multiple ways to reach consumers, communicate

with them, and measure their preferences and purchase-related behaviors (Hennig-Thurau et al., 2010). Based on this personalized knowledge, Social Media enables firms to reinvent customer relationships, by engaging customers in marketing campaigns, product development and innovation. Customer Engagement emerges as a core concept and implies customers’ involvement in a new type of relationship with the enterprise, characterized by co-creation of knowledge, offers, products and value (Giannakis-Bompolisa and Boutsouki, 2014). It can be considered an intimate long-term relationship with customers that results in different behavior such as word-of-mouth (WOM), blogging, writing reviews and recommendations or helping other customers (Van Doorm, 2010).

Social media platforms can facilitate business transformation, improving the management of customer relationships, brand assets, and business processes. However, there is a growing skepticism about its real efficacy, and there is a lack of evidence that confirms a return on investment for companies that have invested in this technology (Rishika et al., 2013). To justify the significant resources and investments in Social Media, executives need to develop and quantify Social Media metrics, such as Customer Engagement, to empirically examine if these tools are creating value for the firm (Luo et al., 2013). Social Media use is a

very recent phenomenon among firms at the real world and, consequently, research on the topic is in its early stages. Additional studies are needed to better understand how firms can leverage Social Media use to create business value (Braojos-Gómez et al., 2015). To shed light on the topic, in this study we seek to answer the following research questions: 1) What are the main Social Media tools that companies are using?; 2) What is the impact of using these tools in Customer Engagement, and how can we measure it? Both questions are of practical importance because companies are investing considerable time, money and effort in their implementation of those tools, but little is known about their benefits. To examine the topic, we conducted a multiple linear regression analysis based on a sample of 212 hotels in Spain.

The article is organized as follows. After a literature review, the empirical study and main results are described. The conclusions, along with some future research lines close the study.

BACKGROUND

Social Media Use

In the last decade, Social Media has emerged as a real ‘game changer’, putting the customer at the center of the organization (Smith and Zook, 2011). It could be argued that Social Media represents a revolutionary new trend for companies (Kaplan and Haenlein, 2010), and some even assume it as the biggest change since the industrial revolution. Social media has changed the way individuals interact with each other and is redefining the way firms connect with their customers (Rishika et al., 2013).

Deepening on the concept, Social Media refers to a set of online tools that supports social interaction between users, facilitating the creation and sharing of knowledge, and transforming monologue (company to customer) into dialog (Hansen et al., 2011). One of the most accepted definitions of Social Media is the one proposed by Kaplan

and Haenlein, (2010, p. 61), who consider it as “a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0, and that allow the creation and exchange of User Generated Content”. Thus, Social Media are browser or mobile-based applications that allow users to easily create, edit, access and link to content and/or to other individuals (Cabiddu et al., 2014). Its content comprises text, pictures, videos, and networks and includes tools such as discussion forums, blogs, microblogging, texting, chat, social networking sites, wikis, photo and video-sharing sites, and review sites (Hennig-Thurau et al., 2010). All these Social Media tools support the democratization of knowledge and information, transforming individuals from mere content consumers into content producers (Berthon et al., 2012). Social media enables firms to converse about their offerings with customers interactively while also providing them the opportunity to share information about products, so it has provided firms with a new tool for customer engagement (Luo et al., 2013). Although those tools are not specifically designed for organizational purposes, companies are integrating their use into their CRM strategies in order to augment customer-firm interactions and reinvent customer conversations.

Social Media have become incredibly popular in recent years. Facebook is the largest Social network in the world. The number of daily active Facebook users has already reached 890 million by December 2014, an increase of 18% over the prior year (Facebook, 2015). User-generated content (UGC) has become a mass phenomenon, with Facebook, YouTube, Wikipedia, and Twitter all being listed among the Top 10 global websites, in number of visitors and page views (Alexa, 2015). This surge in popularity has extensively increased online user-generated content (UGC) or word of mouth (WOM) and hence, attracted marketers’ attention. Burson-Marsteller (2012) empirically examined Fortune Global 100 companies’ social media activity on Twitter, Facebook, YouTube, Google Plus and Pinterest. They observed how

the vast majority of companies (87%) were using at least one of the major social platforms to communicate with online stakeholders, mainly Twitter (82%) and Facebook (74%). The study shows also an interesting trend in the increase of content creation among the examined companies. Since 2010, it has been remarkably how those companies' use evolved from broadcasting to customer engagement with content creation. Companies are now integrating more original multimedia content to share with followers on Twitter, Facebook and YouTube (Burson-Marsteller, 2012).

Parallel to this growth in the business world, research on Social Media has accelerated in the last few years. Some areas of research are rapidly developing, whereas others are nascent or nonexistent (Aral et al., 2013). Despite this quick development in recent years, the study of Social Media is still considered to be in its initial stages (Braojos-Gómez et al., 2015). In this vein, different authors highlight that measuring the impact and value of Social Media on individuals and firms warrants a great deal of additional attention (Dong and Wu, 2015; Rapp et al., 2013). Despite the prevalent use of Social Media by consumers and marketers, empirical research investigating its economic value still lags (Goh et al., 2013). Prior marketing research suggests that recent metrics, such as Customer Engagement, are expected to have a stronger predictive relationship with firm value creation, but empirical evidence on the topic remains scarce (Cabiddu et al., 2014).

Customer Engagement

Customer Engagement has become one of the most important research topics for marketing scholars today (Van Doorn et al., 2010). In essence, it focuses on satisfying customers by providing superior value to build trust and commitment in long-term relationships. Engaged customers become partners who collaborate with sellers in the value-adding process to better satisfy their needs, as well as the needs of other customers (Sashi, 2012).

Given that the concept of Customer Engagement is relatively novel and is still in a developmental phase, there are differing and at times conflicting opinions regarding its conceptualization (Kumar et al., 2010). The most accepted conceptualization, which has been more cited in recent literature is the one proposed by Van Doorn et al. (2010). These authors define Customer Engagement as the *customers' behavioral manifestation toward a brand or firm, beyond purchase, resulting from motivational drivers. It include a vast array of behaviors including word-of-mouth (WOM) activity, recommendations, helping other customers, blogging, writing reviews, and even engaging in legal action* (Van Doorn et al., 2010, p. 253). Customer Engagement is considered as a behavior that is not limited to simple transactions, because engaged customers contribute to firms in many ways that are beyond direct purchases (e.g., WOM, new product ideas, etc.). Porter et al., (2011) proposed a behavioral definition of Customer Engagement and define it as a class of behaviors that reflects community members' demonstrated willingness to participate and cooperate with others in a way that creates value for themselves and for others—including the community sponsor. Customer Engagement emerges as a new core focus for firms in the current environment and entails an emotional involvement of customers to a new type of relationship with the firms, characterized by transparent communications and co-creation of knowledge, products and value.

Embracing an inclusive, behavioral definition of the concept, we considered that Customer Engagement includes: word-of-mouth (WOM) activity, browsing and consuming consumer-generated media contents, content contribution, active participation in online communities, user-generated reviews and recommendations (Cabiddu et al., 2014; Van Doorn et al., 2010). The interactive nature of Social Media with its ability to establish conversations among individuals and firms and involve customers in content generation and value creation has excited practitioners with its potential to better serve customers and

satisfy their needs (Sashi, 2012). For managers, achieving a high level of consumer engagement is viewed as desirable, because it may enhance not only a company's reputation and brand loyalty, but also customer purchase decisions (Dijkmans et al., 2015). The relational consequences of consumer engagement may include commitment, trust, consumers' emotional brand attachment and loyalty. Consequently, executives not only believe that high Customer Engagement is necessary for future growth, they also believe that low Customer Engagement is detrimental to success, both due to lost sales and negative WOM (Kumar et al., 2010).

Social Media use is now a golden opportunity for firms and it represents a cornerstone to start building Customer Engagement. In the following section presents an empirical study covering both topics.

EMPIRICAL STUDY

Methods and Data Collection

The hotel industry was chosen for conducting the empirical study because tourism is an important and extremely competitive sector, which is characterized by its innovative behavior (Orfila-Sintes and Mattsson, 2009). In addition, there is an overwhelming requirement for academic exploration into how hotels can exploit Social Media tools, for improving customer relationships (Jung et al., 2013). Hospitality is one of the most relevant activities within the tourism sector, which has itself become increasingly important, as a source of economic and social development. This study looks particularly at hotels within Spain; since it is considered a World's Top Tourism Destinations as top the rankings by both international arrivals and receipts. Following data from the World Tourism Organization, in 2014 Spain was the second country in tourism earnings worldwide (and first in Europe) with US\$ 65 billion in 2014, and was third in arrivals with 65 million overnight visitors (World Tourism Organization, 2015).

In order to empirically examine the phenomenon under study, a sample of 1000 hotel businesses was selected randomly from a database from Turespaña (Spain's Ministry of Tourism). The key-informant methodology was employed to collect the appropriate information, choosing the hotel managers as informants. Based on the literature review, we drew up a structured questionnaire and it was sent by mail to hotel general managers. We obtained a sample of 212 valid responses, which gave an approximate response rate of 21.2%. The possibility of non-response bias was checked by comparing the characteristics of the respondents to those of the original population sample. A series of chi-square and t-statistics revealed no significant differences between the respondents and the sample, between early and late respondents or based on the type or size of hotel. We also analyzed the non-existence of significant differences based in the geographical location of hotel.

Regarding the profile of the respondents, focusing on the size of the hotels, most of them were small hotels: 75.9% had less than 50 employees, and 24.1% were medium and large hotels. The majority of the sample has three (45.8%) and four stars (47.2%), and with regards to the ownership or property regime of the hotels, most of them were independent (67%) while the rest were integrated in chains.

Use of Social Media Tools

To examine the usage of Social Media tools in the studied hotels, the following tools were included in the questionnaire, as they proved to be the most used in the hotel sector (Sigala, 2011): blogs, microblogging (Twitter), social networking, video-sharing, photo-sharing and review sites. First at all, we examined the percentage of hotels who affirmed be using this tools for managing customer relations. As the authors conducted a previous study on the topic, also in the Spanish hotel sector, some years ago (Garrido-Moreno and Lockett, 2014), we compared longitudinally

Figure 1. Longitudinal analysis of the use of Social Media tools

how the use of those tools has evolved. Prior data was collected in 2011, based on a similar sample (N=210).

Figure 1 shows the use of these tools in hotels both in 2011 and 2015 (expressed in percentage), so we can observe their different level of penetration in the studied industry.

The most used tools in both periods were review sites (more than 99% of hotels reported using tools like TripAdvisor in 2015) and social networks. It was observed also how the use of most of the tools experienced a great increase among those years. Specifically, microblogging (Twitter) was the tools that experienced higher growth (from 19.5% of hotels to 64.2% in 2015). In order to know if the temporal differences between the use of those tools were relevant and statistically significant, the *Mann-Whitney U* test on difference between means was applied, as the data were not normal. We conducted these analyses for the six mentioned tools. As the bilateral critical level was lower than 0.05 ($p=0.00$ in all the cases), it was accepted that the difference of means was statistically significant in the use of all the tools examined: blogs, microblogging, social networking, video-sharing, photo-sharing and review sites.

Focusing on data obtained in 2015, we also asked hotels about their frequency of use of those Social Media tools, in order to obtain a more refined and accurate measure of their actual use of them. We included a specific question in the questionnaire and the range for measuring how often do they use each Social Media tool ranged from 1 (never) to 7 (every time). The average frequency of use of each tool is reflected in Figure 2.

We can see how review sites and social networks were, by far, the tools used with more frequency (their averages values were 6.41 and 5.32 respectively). So sampled hotels have integrated them into their daily activity in order to communicate with customers, gaining knowledge from them and establishing valuable conversations. Tools like microblogging, video-sharing and photo-sharing were used more occasionally and blogs were the less frequently used platform. If we compare the level of penetration of the different tools and their frequency of use, we found that results seem coherent. However, it is surprising to observe how microblogging, despite their high level of penetration (64.2% of hotels were using it in 2015); was not used as frequently as other tools (average frequency of use: 3.57 upon 7).

Figure 2. Frequency of the use of Social Media tools

Results show how the use of Social Media tools has become massive, especially in tourism firms, like hotels, where customers are making increasing use of the Internet as a tool to express their experiences with organizations, and potential consumers make purchasing decisions, on the basis of the information found on the Internet (Haro de Rosario et al., 2013).

We have observed how review sites, like TripAdvisor, have the higher level of penetration in this sector, and are the most frequently used tool. TripAdvisor-branded sites comprise the largest travel community in the world, with user-generated recommendations and international hotel reviews attracting more than 260 million users a month (Google, 2014). The system provides users with independent travel reviews and comments written from other members and provides a powerful platform for interaction and sharing experiences (Cabiddu et al., 2014). Consequently, our findings confirm that TripAdvisor handling is a strategic priority for the hotels analyzed.

Apart from review sites, the Social Media platforms that showed the highest frequency of use were social networkings sites and microblogging. These results are coherent with other studies conducted in the Spanish hotel sector (Escobar-Rodríguez and Carvajal-Trujillo, 2013; Haro de Rosario et al., 2013). The greater presence of

hotels in platforms like Facebook and Twitter is easy to understand, because they have the most users and provide a substantive part of the available online word-of-mouth (Dijkmans, 2015). The reported use of video and photo sharing services as Youtube and Flickr was also high (more than 60% of hotels used those platforms), as they allow a dynamic relationship with the users and a greater interaction with them (Escobar-Rodríguez and Carvajal-Trujillo, 2013).

Impact of Social Media use on Customer Engagement

To empirically test this impact, we conducted a multiple linear regression as estimation technique. To measure Customer Engagement, we introduce five items in the questionnaire based on previous studies (Van Doorn et al., 2010; Verleye et al., 2014), referring to: customer feedback; customer involvement in marketing decisions; WOM activity; customer recommendations and strategic relevance of WOM. A summative index of customer engagement was calculated as the average of all these items, and was considered the dependent variable. The frequency of use of the six mentioned tools were introduced as independent variables. Two control variables (firm size and age) were also included in the model.

Table 1. Descriptive statistics and correlations

		Mean	SD	1.	2.	3.	4.	5.	6.	7.	8.
1	Firm size	47.79	76.05								
2	Firm age	24.22	24.25	.208**							
3	Customer Engagement	5.39	1.20	.193**	-.064						
4	Frequency of use of Blogs	2.50	1.89	.166*	-.005	.182**					
5	Frequency of use of Microblogging	3.57	2.38	.136*	-.043	.240**	.501**				
6	Frequency of use of Social Networking	5.42	1.81	.207**	.015	.328**	.401**	.547**			
7	Frequency of use of Video-sharing	3.19	1.99	.232**	.007	.299**	.478**	.473**	.489**		
8	Frequency of use of Photo-sharing	3.11	2.10	.202**	-.067	.213**	.538**	.481**	.455**	.677**	
9	Frequency of use of Review Sites	6.31	1.13	.117	-.074	.362**	0.083	.132	0.118	.128	.121

Notes: N=212; * $p < 0.05$; ** $p < 0.01$ (two-tailed)

The descriptive statistics and correlations for the variables are reported in Table 1.

An assessment of multicollinearity was carried out through the computation of tolerance value and variable inflation factor (VIF). For all the variables, the tolerance values were well above

0.4 cutoff and the VIFs were substantially below 10 cutoff, indicating multicollinearity was not a problem.

Results of the regression (See Table 2) show how the use of three of the six SM tools examined directly influenced Customer Engagement. These

Table 2. Results of multiple regression analysis

Variables	Model 1	Model 2
Step 1: Control Variables		
Firm size	.216**	.101
Firm age	-.109	-.071
Step 2: Dependent Variables		
Frequency of use of Blogs		.001
Frequency of use of Microblogging		.021
Frequency of use of Social Networking		.208**
Frequency of use of Video-sharing		.174*
Frequency of use of Photo-sharing		-.073
Frequency of use of Review Sites		.304***
R ²	.049	.244
Adjusted R ²	.040	.214
ΔR^2	.049***	.174***
F	5.355**	8.18***

Notes: Regression coefficients are reported as standardized β values; [†] $p < .10$, * $p < .05$, ** $p < .01$, *** $p < .001$.

variables were: social networking ($\beta=.208$, $p < .01$); video-sharing platforms ($\beta=.174$, $p < .05$) and review sites ($\beta=.304$, $p < .001$). Consequently, the use of these variables can be considered a relevant enabler of Customer Engagement. Surprisingly, blogs, microblogging and photo-sharing platforms were not directly related to customer engagement. F test on all adjusted R squared changes were significant; indicating that successive variables added in the regression models significantly improved the prediction for Customer Engagement.

Our findings support prior studies indicating that Social Media technologies are key enablers of Customer Engagement (Harrigan et al., 2015). Nevertheless, we examined the phenomenon in a more detailed way, analyzing the specific impact of the six more relevant Social Media tools. We observed that review sites were the one that showed the highest impact in Customer Engagement. These results are coherent with existing literature that indicates that platforms like Tripadvisor have become essential for managing online reputation, particularly in the hotel sector (Baka, 2016).

Similarly, Social Networking use proved to be determinant in fostering Customer Engagement. Nowadays, channels like Facebook, have changed marketing practices and are used for gaining an audience and communicating campaigns, offers and news (Baka, 2016). Our results are coherent with Dijkmans et al. (2015) and suggest that companies are increasingly trying to get consumers engaged in online discussions by including social networking sites like Facebook into their communication strategy.

Regarding Video-sharing platforms like Youtube, results also show that its use can be considered a determinant of Customer Engagement. YouTube focuses on video clips posted online by private and corporate users, and approximately more than two billion clips are watched daily (Mansson, 2011). Consequently, Youtube is a very dynamic platform that offers hotels multiple possibilities for engaging customers.

Finally, results show that the use of Microblogging, Photo-sharing sites and Blogs seems not to be directly related to Customer Engagement. Surprisingly, despite the increase in the level of use of Twitter, findings show that this use is not having a real impact in enhancing customer-engaged behavior. We have to point out that Twitter enables fast, brief conversations; and sometimes hotels are using it exclusively as a promotional tool (Jung et al., 2013), so it is important to keep content focused, occasional, and appropriate instead of a bombardment, which could be very harmful. It is interesting to note also that Twitter in comparison to Facebook has different user demographics, so hotel managers need to acknowledge this differences and develop exclusive strategies and customize content appropriately to each social network (Jung et al., 2013).

CONCLUSION AND FUTURE RESEARCH LINES

In the current 2.0 environment, Social Media tools have completely changed the way companies relate to the market, opening a wide range of new possibilities. Customers are more connected than ever and are using tools like Facebook, Twitter, Youtube, Flickr, and review sites such as Tripadvisor, on a daily basis. Traditional CRM have evolved towards Social CRM strategies, and companies have integrated Social Media tools into their marketing strategies to engage customers in open and active conversations, building emotional bonds with them. However, despite the eagerness on the part of firms to embrace Social Media, there is also much skepticism about its efficacy.

The present study focuses on the concept of Social Media use and Customer Engagement, exploring the level of use of these tools in a longitudinal way; and examining also how the use of these tools can create value for firms by fostering Customer Engagement.

Regarding the use of Social Media tools, we observed that the most popular tools employed by

the examined hotels were review sites and social networking. Hoteliers actively managed *TripAdvisor* reviews and acknowledged having an active presence on social networks, like *Facebook*. We also examined the phenomenon longitudinally (with data from 2011), and we observed a significant increase in the use of the six analyzed tools. Results of the regression show that three Social Media tools: review sites, social networking and video-sharing platforms appear as key enablers of Customer Engagement. Findings highlight how Social Media technologies are reinventing customer relationships and can be considered a basic enabler of customer engagement, supporting prior research (Harrigan et al., 2015).

This study has interesting implications for academics and practitioners. Given that Social CRM is a topic of practical relevance nowadays, the study provides useful implications for managers, as it shows not only which are the most used Social Media tools, but also which have a bigger impact on customer relationship, enabling customer-enabled behaviors. Based on this evidence, managers can readjust their Social Media strategies, promoting the use of the most effective tools. Regarding future research lines, this study proposes that it would be interesting to analyze the use of these tools in different sectors, comparing the differences between services and manufacturing companies. Secondly, it would be necessary to examine not only the impact of Social Media on Customer Engagement, but also its effect on organizational performance.

KEY TERMS AND DEFINITIONS

Blogs: Websites owned and written by individuals who maintain regular commentaries, consisting of discrete entries (“posts”) displayed in reverse chronological order.

Customer Engagement: behavioral manifestation toward the brand or firm that goes beyond transactions. It involves the creation of a deeper, more meaningful connection between the company and the customer, and one that endures over time.

Microblogging: Social networking services that enable users to send and read very short messages, usually restricted by the number of characters (e.g., Twitter allows 140 characters per message).

Picture-Sharing Websites (e.g. Flickr) and Video-Sharing Websites (e.g. YouTube): Online platforms that allow users to store and share images and videos.

Review Sites: Websites on which reviews can be posted about people, businesses, products, or services (e.g., TripAdvisor).

Social Networking Sites: Online platforms on which users can find and add friends and contacts, send messages to friends, and update personal profiles (e.g. Facebook).

INTRODUCTION

The healthcare sector in the XXI century presents a big technological development that covers a broad knowledge. All fields of medicine are deepening their knowledge, which increases the volume of material that must be handled by professionals in each specialty. This large volume of material should be taken into account by health professionals, because it contributes to a better quality of care.

The mode of transmission of this knowledge to professionals is usually through training courses in their own work areas (internal instruction) or outside the centers (external instruction). New technologies have entered the world of education, leading to changes in the way people teach and learn. The traditional way of teaching has been face-to-face classes; however, with rising technologies, virtual training via computers and virtual teachers are being implemented in some institutions. This change in the way of teaching also leads to changes in how to assess the knowledge gained through this method of learning.

The aim of this paper is to provide a small analysis of online training courses for health professionals, and deepen into an appraisal system developed to integrate different complementary

variables, and how they can be implemented as a method addressed to assess online courses in a more comprehensive way.

BACKGROUND

Health Training

Health training is a complex field; several areas of knowledge and practice make necessary an update in instructional and teaching methodologies (Schoonheim, 2014; Frenk, 2010; Horton, 2010).

There are many examples of instructional needs in the field of health. Many medical specialties (e.g. primary care, surgery, or oncology) require continuous training and up-to-date of professionals to provide the best patient care. Doctors, nurses, and technicians, all of them attend courses or educational programs in order to improve their knowledge or skills in each specialty.

One example is Evidence Based Medicine (EBM). It is based on the principle that medical decision making is achieved by integrating the best available evidence with clinical expertise and patient values. When teaching EBM it should integrate core knowledge with clinical practical

activities. This will lead to taught EBM with a variety of modes: lectures, tutorials, online, problem based or self-directed learning (Straus 2011; Del Mar, 2004).

Not only the health areas but also the professionals in medical specialties have troubles with their instruction/training. General practitioners (GPs) struggle with several barriers to the use of EBM related to insufficient knowledge and skills. They also find barriers related to their practice and patient population such as lack of time, patient-related factors or a lack of available evidence (Mayer 1999; Zwolsman 2013; Te Pas 2013).

Standalone teaching improves student knowledge, but not skills, attitudes or behavior in EBM. Non randomized clinical trials indicated that integrating teaching of EBM with clinical activities (blended learning) was associated with improvements across all four domains: knowledge, skills, attitudes and behavior (Coomarasamy 2004). In the results of randomized controlled trials, the authors concluded that any form of teaching, including lecture, tutorial, self-directed, online, problem-based, multidisciplinary, was associated with an increase in EBM competency (Ilic 2014).

A comprehensive meta-analysis recently conducted by Teachers College (Columbia University) (Means 2013), indicated that students in online classrooms had moderately better performances than those receiving instruction in traditional classrooms (Milic 2016).

In the Ilic's study students's perceptions were positive about using the BL approach in teaching and learning about EBM (Ilic 2015). They developed a three-step approach (i) self-directed learning through online multimedia presentations, (ii) discussion and activities in class, and (iii) application in practice. This method was positively received by students. Students involved in the BL approach found the content was useful, engaging and well-targeted to their level of competency and suggested that blended learning could be strengthened by introducing a journal club to small group activities early in the curriculum, providing an opportunity to learn in a group environment.

This could be similar to the “forums” created on e-learning platforms to debate issues or questions about different fields of knowledge.

Some other studies appreciate that e-learning alone will increase EBM knowledge but it is not effective in increasing EBM skills and changing EBM behavior. They recommended a blended learning course, because BL includes different learning or instructional methods, different delivery methods, different scheduling and different levels of guidance (Pankin 2012). An intensive blended learning course on EBM for GP trainers enables an increase in knowledge and skills that remains after four months. However, attitude and behavior towards EBM show no differences before and after the intervention (Te Pas 2015).

Training Methods

The classical training methods consist in classroom lectures with students and teachers together. Lecture is a simple and fast method to present the vast issues addressed to a high number of learners. Some disadvantages of this method are long periods of time, inactiveness or absence of the students, or fast forgetting of the subject. When students have control over the learning methodology, it is called a “learner-centered” model of teaching. The role of the teachers in this context is to facilitate knowledge acquisition (Bahner 2012; Ruiz 2006; Boulos 2006; Koops 2011; Cook 2010).

Traditional learning must be stepped at a specific time and place and is considered essential in building a sense of community. New technologies have grown in educational world, driving to changes in teaching methods (Kemp 2014; Conole 2008).

E-Learning refers to the educational system in which teachers and students are separated by physical distance, but the technology allows them to learn together: it is the online way of knowledge. This system has its own limitations: there is no human interaction and communication regarding to a face to face classroom (Thiele 2003; Twomey, 2004). Online education is growing rapidly, pro-

viding new and useful instructional elements in different professional fields (Slotnick, 2000; Cook 2008; Hugenholtz 2008; Zolfaghari 2007). It can not only improve suitability and effectiveness for individualized and collaborative learning, but also it can provide up-to-date information through the use of interactive multimedia (Choules 2007; Cook 2007; Yu 2006; Peng 2014; Wu 2010; Moreira 2015).

E-courses are becoming more popular because of the didactical advantages they offer, such as the possibility to adapt them to individual learning styles (Nilsson 2012) as well as the possibility to repeat courses (Sun 2008; Ellaway 2008). The logistic benefits, such as learning at any convenient time or anywhere in whatever place and using different devices, are also important advantages of e-learning (Wutoh 2004; Curran 2006; Choules 2007).

Blended education or blended learning (BL) combines two or more modalities that use other teaching methods than online courses (e-Learning), in addition to the traditional classroom lessons (Anderson 2005). Teaching styles are based on the concept that individuals differ with respect to what mode of study is most effective for them. Results of some trials show that students prefer an integrated learning methodology with different learning styles, and they are supporting the use of the BL approach (Pashler 2008; Grasl 2012; Lehmann 2013; Ilic 2015).

The *hybrid* instructional model is a blend of conventional face-to-face instruction and Web-based distance learning: a mix of both classroom face-to-face meetings and distance learning. Blended learning utilizes the best online tools to support a teacher led classroom. In blended learning scenarios, “face time” between students and teachers is not replaced by online course delivery. Hybrid learning focuses less on the technology and more on the most effective way to deliver a course to learners. In hybrid learning, a significant portion of the course takes place online. Blended and hybrid learning both will be very effective

because of the synergy that is created between different ways of studying.

Online and face-to-face traditional formats have their own respective strengths and weaknesses. Neither is better: they are complementary. This confirms the benefit of BL, which includes a combination of face-to-face and online learning methodologies integrated into a single course (Osguthorpe 2003; Garrison 2008). Research has suggested that well organized online classrooms are as effective and of comparable quality as traditional classrooms (Zebrack 2005; Cook 2008; Aggarwal 2011).

The main advantage of web-based education is its flexibility, allowing students to access content from several locations, at any time. It encourages self-management learning, with the ability to exchange links to related information (Baldwin 2001; Fieschi 2002; Harden 2002; Lewin 2009).

Appraisal Systems

The usual appraisal systems for official teaching and training are often based on objective tests checking knowledge acquisition, attendance control, delivery of practical works to improve clinical skills, and participation in classes, tutorials or seminars. Tests are mainly used as a way to assess students because there is evidence that they stimulate learning by increasing retention of the information (Roediger 2006; McDaniel 2007).

Evaluation methods of online courses should collect the objectives sought in each course or training. These objectives for online distance learning are represented by five areas:

1. Incorporation of learning principles and strategies.
2. Inclusion of real problems.
3. Inclusion of decision-making, or problem solving.
4. Inclusion of practice in evaluating viewpoints.
5. Development of interactive activities which drive to discussion and critical thinking.

To develop the methodology of on-line instruction, traditional appraisal systems may not be suitable, and some of them lose their objectivity. New assessment methods should be implemented, showing in a comprehensive manner and as objectively as possible, the development of students in the subject taught and their work progress (Casebeer 2004; Weston 2008; Freire 2012).

The Comprehensive Appraisal System of La Ribera University Hospital

La Ribera University Hospital (Alzira, Spain) periodically implements training courses for health-care professionals assigned to the corresponding Department, and addressed to all employees that integrate this Department.

It has been delivered online training courses for several years in the health field, based on the Campus Ribera, a corporate virtual platform implemented in our Department of Health, which has allowed the organization, to evaluate the methodology and performance of these courses (Monroy Anton 2011, 2013). In this field we have developed what we call the “*Comprehensive e-Learning Appraisal System*” (CeLAS), which aims to categorize and score each of the elements of learning/instruction, resulting in a final assessment for students very close to objectivity and fairness.

These training courses are developed electronically through the corporate platform *Campus Ribera* using a Moodle platform. Campus Ribera started in 2009 as a learning platform that allows optimizing the traditional training process by using online learning methods (Izquierdo et al, 2014). This virtual platform is managed from the institution, and teachers (tutors) are qualified professionals of the Department of Health.

After several years of developing different types of courses, the final assessment to obtain credits or certificates was very heterogeneous because the test systems were different: only the

connection to the course, meet a minimum number of input records online, make some assessment test, some drafting work, etc. None of them were perfect and contrast the existence of groups of students more interested and participatory compared to other more passive groups. Thus, the ultimate goal of the courses is distorted because the training of some professionals would not be that expected and motivation to achieve these courses would only be addressed to obtain certificates for merely passing the course.

To standardize somehow this deficiency and improve the quality of the course and the training of students it is designed a system of evaluation to attack different parts and elements, weighting each one according to the relative importance that teachers would give them, and resulting in a final note or score. We have called this system: “*Comprehensive e-Learning Appraisal System*” (CeLAS).

CeLAS was initially implemented in a blended course entitled “*Approach to the toxicity of treatments with external radiotherapy*”. It lasted 6 weeks, with a workload of 25 hours (mixed classroom and online) and it was accredited by the National Education Commission of Spain with 3.6 credits. They were accepted for the course seven students, based on the best ratio student/teacher parameters previously analyzed for our blended courses (Monroy Antón 2013).

Assessment Method

Three areas of training (blocks or sections) were proposed, with a system of weighted score for each one of a total of 100 points as it is displayed in Figure 1):

Area/Block I: Assessment of knowledge, representing 70% of the total score.

Area/Block II: Assessment of participation, representing 15% of the total score.

Area/Block III: Assessment of practices, representing 15% of the total score.

Figure 1. Areas of training

Final Course Certificate

For the final course certificate, students must achieve the following objectives:

1. Exceed 50% of the total points of the final evaluation.
2. Not obtain a score of zero in any of the three aforementioned evaluation blocks.

Methodology of Evaluation of Each Block

Evaluation of Block I

Assuming a total of 70 points which were obtained by performing knowledge test corresponding to each of the different thematic units (T.U.) of the course, and a final overall evaluation test (as it is shown in Figure 2).

Evaluation of Block II

Weighted with a total of 15 points. They were obtained by the participations of students in specific forums for each thematic unit. These entries were evaluated according to the type of response issued by the students (Figure 3):

- 0 points = not answered;
 1 = unsatisfactory;
 2 = satisfactory;
 3 = above expectations.

The final grade of the evaluation block result of the sum of average scores in all forums, with a maximum possible score of 15 points.

Figure 2. Evaluation of knowledge

For the evaluation of forums, students must meet minimum requirements:

- It was mandatory to answer the specific forum “*Case Report*”. In the case that there was no participation in this forum, the rating would be zero in the entire block.
- To obtain the score greater than zero in at least three of the four forums on thematic units.

Evaluation of Block III

Weighted with a total of 15 points. Related to works proposed by teachers and delivered by students by electronic means, and a test with questions about the practical issues discussed during the course. The grading of the work was as follows (Figure 3):

- 0 points = not answered;
 1 = unsatisfactory;
 2 = satisfactory;
 3 = above expectations.

The final score of the block assessment result of the sum of average scores for all jobs, the maximum possible score was 15 points.

For these scores, minimum requirements had to be met:

Figure 3. Evaluation of participation (forums)

- The fulfillment of the test of practice was mandatory.
- Achieving greater than zero score in at least three of the four papers offered in the thematic units.

Students' Work Monitoring

To guide students on their progress throughout the course and the scores on each of the blocks and tasks, Moodle offers the possibility of gathering information through the *Gradebook* which monitors student's activities. The *Gradebook* in Campus Ribera allows tutors to organize and manage information about the students in online courses. For example, by displaying the scores obtained through objective tests or grading the delivery of assignments or forum participation. It also enables the aggregation of the different assessment sources in order to get a final grade.

FUTURE RESEARCH DIRECTIONS

The Global World leads to the use of new technologies for most of our daily activities. One of them is education. Training systems via e-Learning are gradually imposing traditional education methods,

allowing long distances formation of large population. However, this ability to communicate and learn knowledge should be assessed as objectively as possible, combining performance parameters and elements, so we must investigate in the development of new evaluation systems.

Recent studies suggest that a combination of face to face training with online instruction based on e-learning methods is more flexible than other methods (Garrison 2004).

The online learning paradigm offers valuable tools that could supplement or replace aspects of the traditional lecture-and-textbook-based approach to teaching and learning (Glazer, 2012).

Blended learning attempts to create an optimal learning environment by combining a variety of learning approaches (lecture, tutorial, online, problem-based and clinical) to deal with different learning styles and requirements. Some trials have evaluated the effectiveness of the BL model in medicine (Grasl 2012; Lehmann 2013; Masie 2002).

The asynchronous ability to exchange information, cost-saving, personalized learning, increased accessibility, ease of distribution and updating content are some examples of the advantages offered by the online classrooms. Studies and literature reviews show that technology based

learning improves student knowledge acquisition which requires abstract conceptualization and reflective observation, but adversely affects student ability to obtain knowledge requiring concrete experience (Hui 2007).

The meta-analysis performed by Liu (2016) concludes that blended learning has a large consistent positive effect on knowledge acquisition compared with other modalities (pure e-learning, face-to-face, or no intervention) and may be more effective than other ways of learning. They concluded that blended learning was very effective and educationally useful in health professions. Possible explanations could be:

1. Compared with traditional learning, blended learning allows students to review electronic materials as often as necessary. It likely enhances learning performance (Wu 2010).
2. Compared with e-learning, blended learning learners are less likely to experience feelings of isolation or reduced interest in the subject matter (Hara 2000; Maki 2000).

Analyzing each unit of the toxicity course, acquired knowledge of study matter improved the previous level that brought the students before the end of the teaching of these subjects. This was observed conducting tests before the study of the issues of each thematic unit and after teaching the same knowledge. The difference between the scores before and after training in other studies, led to increased knowledge scores in participants (Unal 2005; Koch 2005; Woo 2000).

Tests are considered the standard and principal ways of assessment for several courses. The implementation of a medical program with tests is developed in order to stimulate learning: after an initial contact with the learning material, being tested increases information retention more than reviewing that material again. Also the number of tests increases the effect of this system (Larsen 2008, 2009; Kerdijk 2013; Wood 2009; Karpicke 2008). Some institutions have created platforms

that employ test-enhanced methodologies to teach learning materials (Taveira 2014).

The activities that can help learners to apply knowledge from the courses are exercises, quizzes, self-assessment test; but also discussion cases, forums interactivity or many others. These are the items that the faculty of courses should evaluate.

Prospective trial conducted with third year medical undergraduate students attending the Faculty of Medicine of the University of Belgrade (Milic 2016) compared two methods of education: blended learning and traditional on-site. Students were asked to choose their learning method at the beginning of their course. The evaluation system was identical for both learning modalities:

1. Course activities throughout the year,
2. Written knowledge test,
3. Final exam.

On a similar way, Larson reported no significant differences among three education delivery methods (on-site, online, and blended learning) as measured by exam scores and final grades. The study concluded that online and blended methods are at least equivalent to the face-to-face one (Larson 2009).

As we can see, most work on evaluation of online courses use multichoice test, as used by us. A simple way is to establish a classification or numerical evaluation of knowledge. However, increasingly we turn to complete this evaluation with other activities, which should complement the results of the test.

Systematic or comprehensive appraisal is not common practice. Other ways for monitoring courses are observing participation and satisfaction. Appraisal should be driven not only by the test results but also other complementary issues such as skills or tasks proposals through problem-based methods (Kreber 2001; Wilkes 1999).

The future will probably be the implementation of courses tailored to the needs of students with online high probability. Evaluation systems

of these courses must be adapted to each of them, but mainly to the following facts: the group of students to whom it is addressed, the objectives pursued in the course, course duration, the scope for action of the students. Evaluation systems as developed in our hospital can serve as a model or basis for developing other more complete, complex, or just different, but adapted to the group of students that the course addresses.

CONCLUSION

In our experience of an online radiotherapy course, all students (100%) reached the minimum final score required in the course, fulfilling the objectives of each subject and evaluation block and obtaining the corresponding certificate. The results showed that students were getting better as performing the various blocks of the course which were arranged in a table of grades, so that students could see at any time their partial and overall marks knowing their score to overcome the required minimum for the final course certificate.

This “Comprehensive e-Learning Appraisal System” provides a fairly objective assessment method of learning, and can avoid or greatly reduce the subjectivity of the teacher assessment, as grades are displayed automatically, once students do course activities. It can be applied as a tool in the training courses in all fields of health care, and enables holistic assessment jointly with different variables of knowledge, weighting those considered most important in each specific course.

The grades or scores of the course can be accessed whenever by students and teachers by means of items designed specifically for each training activity (e.g. forums or wikis), which are integrated into the module of the course and have each of the graded sections and the corresponding score. It is a demanding system for the student, since it forces pursuing and constant work, reflecting on the final grade this degree of effort. These final

grades also serve to differentiate the use of the training received, positively influencing the professional careers of workers. It is an easy system to implement in courses with an online methodology; it does not require sophisticated virtual tools or complex calculations, since practically all scores of evaluable elements are provided directly from the various items of the learning platform.

KEY TERMS AND DEFINITIONS

Appraisal Systems: Evaluation systems for courses, attending different approaches and methodology of assessment.

Blended Learning: Combination of traditional face-to-face learning and distance (online) methods.

E-Learning: Education based in online courses. Educational system in which teachers and students are separated by physical distance, but the technology allows them to learn together.

Hybrid Learning: Finding the right mix for the student, out of all the possibilities in learning.

Flipping the Medical School Classroom

Kristina Kaljo

Medical College of Wisconsin, USA

Laura Jacques

Medical College of Wisconsin, USA

INTRODUCTION

Teaching and learning in medical schools and institutions is a multifaceted endeavor, especially as the United States' health care system continues to become more complex. Medical students need to develop a rich foundation of not only content knowledge, but also problem solving and technical clinical skills. However, due to various barriers such as inadequate or limited clinical placements, an unpredictable learning environment, and duty hour time restrictions (Feng et al, 2013; McLaughlin et al., 2014; Tainter et al, 2016), medical students may develop gaps in knowledge that could impact their future success. To circumvent these gaps, medical education programs must be innovative in how they deliver core content knowledge. Historically, lecture-based didactics permitted learners to be passive in the acquisition of knowledge, while teaching faculty were recognized as a "sage on the stage" (King, 1993). The role of "sage on the stage" is considered to be the keeper of knowledge and who considers students as empty vessels that need to be filled. This archaic method of interaction and learning is not appropriate in the preparation of today's 21st century medical student (O'Brien & Irby, 2013).

Educational opportunities should be provided in a manner that is learner-centered and innovative to further increase student engagement and deeper comprehension of the required medical knowledge (Irby, Cooke, & O'Brien, 2010; Prober and Heath, 2012). Suggestions from Irby, Cooke, and O'Brien

(2010) assert four goals that are imperative for the future of medical education:

1. Standardization of learning outcomes and individualization of the learning process,
2. Integration of formal knowledge and clinical experience,
3. Development of habits of inquiry and innovation, and
4. Focus on professional identity formation (pg. 5-6).

With these objectives in the forefront, educational theories and practices must be revisited, tailored, in order to improve and evolve current pedagogical practice.

Rapid advancements in technology, both of software and hardware, have encouraged e-learning to emerge as a key component in curricular development, especially in the field of medical education (Dankbaar & de Jong, 2014). Students can now access and interact with required readings, cases, models, videos, simulations, and collaborate with peers across the country or the world. Remarkably, e-learning has allowed educators to "mobilize" their teaching practice and provide content at any point in time, from any location (Jashapara & Tai, 2011). However, there are always challenges when attempting to develop and implement a new e-learning strategy while simultaneously integrating face-to-face contact. Thus, how does an educator integrate both e-learning and face-to-face learning in a balanced

and engaging way? This article synthesizes the method of flipped lectures or flipped learning and presents practical strategies to implement flipped learning within the unique medical education setting.

BACKGROUND

The flipped lecture, flipped learning, or inverted classroom originates from K-12 education (Bergmann & Sams, 2012) and provides students with the opportunity to interact with content prior to entering the classroom in a structured, organized way (see figure 1) (Barett, 2012; Mazur, 2009; O'Flaherty & Phillips, 2015; Lage, Platt, & Treglia, 2000). Flipped classrooms stemmed from the Khan Academy, conceived in 2006 by Salman Khan which provided access to 3200 videos and 350 practice exercises which were used by teachers for flipped classrooms (Bishop & Vergler, 2013).

From there, flipped lectures have steadily grown in popularity following a distinct curricular design. First, students participate in the asynchronous event, commonly recognized as an online component. This typically involves a module with videos, podcasts, interactive readings, reflective questions, and/or chatrooms (Prober & Health, 2012; Sharma et al., 2015). Then, during the face-to-face class time, or synchronous event, students participate in active learning and implementation of new knowledge. Flipped learning is *not* simply assigning homework or readings and then conducting teacher-led lectures. Rather, flipped learning incorporates a diverse amalgam of technology, literature, and inquiry to establish a critical knowledge base prior to engaging with the content on a higher level of learning. In turn, the learning environment becomes personalized, engaging, and content rich, thus improving the ways in which students apply abstract knowledge to solve realistic problems (Bergmann & Sams, 2012; Mann, 2011; Sharma et al., 2015).

Flipped lectures have been found as a successful method to engage students. In a study by Lew (2016) 46 medical students enrolled in an emergency medicine clerkship much preferred the flipped lecture to a more traditional lecture-based classroom. Furthermore, the students in this study remarked on the advantage of the interactivity and medical decision-making. Interestingly, Lindeman et al (2015) discovered with the implementation of flipped lectures, surgical students did not perform any better on the National Board of Medical Examiners (NBME) examination, but that students did give a higher satisfaction rating at the conclusion of their clerkship. Similarly, Liebert et al (2016) found comparable results, when investigating student NBME results from both the flipped lecture to those in the traditional classroom, there was no statistical difference. Notably, student satisfaction of the flipped lecture was higher than the traditional lecture-based classroom with individuals reporting a greater interest in surgical specialties after the clerkship.

Those who support flipped learning have found that this instructional method has a number of benefits (O'Flaherty & Phillips, 2015; Sharma et al., 2015). First, by implementing flipped learning, students learn at their own individualized pace, which is appropriate to their learning style and need. Additionally, students can take advantage of repetition and repeated exposure to the content by pausing or revisiting the material as needed (Pierce & Fox, 2012). Upon entering the physical classroom, students have a foundational knowledge of the required content. This is essential as students and educators now have the space to engage in robust discussion regarding complex cases, problems, and issues. This interactivity also provides for immediate feedback and evaluation (Sharma et al, 2015) to both student and educator regarding what additional knowledge gaps exist. Furthermore, this flipped model encourages students to take ownership of their learning as they are required to be prepared to actively engage to solve problems and address cases.

MAIN FOCUS OF THE ARTICLE

Issues, Controversies, Problems

The traditional United States medical school follows a 2 + 2 curriculum, two years of basic science education and 2 years of clinical clerkships. The clinical clerkships are a particularly unique learning experience as medical students are required to rotate through six or more medical specialties to develop an understanding of diagnosis and health management appropriate for each discipline. Each clerkship has its own entity and student experiences vary due to different clerkship objectives, clinical content, variability in care, and teaching faculty. There is however, a common expectation for clerkships to provide didactic, explicit educational experiences outside of the clinical setting. The Association for American Medical Colleges (2008) asserts that the aim of medical education is to “equip each student to develop the lifelong habit of skill learning and self-assessment, in order to further develop and maintain clinical performance expertise” (p. 5). To do so, students need to be involved in a multitude of hands-on learning experiences to further advance clinical skills, clinical problem solving, and medical knowledge.

The surgical clerkships, or surgical block which typically incorporates obstetrics and gynecology, surgery, and anesthesiology are unique as these are conducted with, “rapid transitions from one discipline to another, one patient population to another, one setting to another, and from one culture to another” (Irby, Cooke, & O’Brien, 2010, p. 84). As such, this fast-paced, transient learning environment becomes a revolving door, quickly pushing medical students through specialties (Bell, et al., 2008; Hammoud, et al., 2006). This revolving door becomes further exacerbated due to the limited time faculty have to plan, teach, mentor, observe, and evaluate medical students (Irby, Cooke, O’Brien, 2010). Thus, this environment further asserts the need for multifaceted, active opportunities which provide for a blended learning

experience. An environment where students learn independently to build a foundation of knowledge as well as interact with peers to engage in critical problem solving to further reinforce the necessary medical content.

Due to the various methods of content presentation, flipped learning has slowly gained popularity among specialties in medical education. Surgery, radiology, obstetrics and gynecology, intensive care, pharmacology, and emergency medicine (Belfi et al, 2015; Heitz et al, 2015; Khanova, et al., 2015; Liebert et al, 2016; Morgan et al., 2014; Tainter et al., 2016) have all explored the implementation of flipped learning with medical students. ‘

The research conducted on the radiology clerkship presented by Belfi et al (2015) employed flipped lectures as a method to address the reduced amount of teaching time from 20 hours to 12 hours. Medical students were given an outline of the topics and the available online modules called: *RadCasts*, *RadTutorials*, *RadGames*, and *Interactive Clinical Anatomy and Radiology Utilization Simulator (ICARUS)*. The *RadCasts* were short 10-15 minute PowerPoint presentations that reviewed the clinical approach to imaging with self-assessment questions students needed to complete. To review specific clinical conditions or a specific patient population, students accessed *RadTutorials*. *RadGames* were more interactive modules that students completed regarding chest diagnosis. The simulator *ICARUS* incorporated online simulation that encouraged students to use various problem-solving skills. The in-class sessions were mindfully planned, taking into consideration the prior knowledge students were constructing with the online components. Case-based teaching was implemented, with students encouraged to use an audience response system, a Jeopardy-type review game was facilitated to build on students’ collaborative skills, and additional face-to-face simulation workshops were facilitated. Overall, this pedagogical design was very successful two-fold, medical students achieved

higher posttests after the flipped classroom and students perceived the inclusion of such diverse teaching practices to be beneficial to their learning.

Of course, with any curricular change, challenges emerge which need to be addressed. “Practical considerations” when implementing flipped learning are documented by Tainter et al. (2016, pg. 4). First is the resistance to change of the traditional medical education framework. The argument being that medical education continues to prepare excellent physicians, why bother changing what has been in place for decades. The second deterring factor is of course, time and cost. Teaching faculty will need to make time outside of their clinical obligations to learn of the various technological resources and how those are implemented with learners. Third is a concern that students will not complete the online assignment(s) prior to meeting in the face-to-face setting. The fourth challenge is “resistance to active learning” (pg. 5), which embodies two constructs. First, there are students who prefer to be passive participants in the learning environment rather than engaging with peers during group discussion. Second, some students may be uncomfortable when teaching faculty put more ownership and responsibility on the learners during case-based or team-based learning experiences. Any one of these barriers may preclude teaching faculty from attempting or successfully integrating flipped learning into the curriculum.

SOLUTIONS AND RECOMMENDATIONS

To alleviate potential challenges in the field of medical education, implementing flipped learning opportunities provides greater flexibility for student and teaching faculty. Students have the ability to view and understand material prior to engaging with the content at a higher level in the classroom. By providing learning objectives online or virtually, teaching faculty have clearly delineated the expectations in the acquisition of

content. Rather than simply assign a chapter to read in a text, employing multiple modalities of technology allows students to further scaffold their learning (Vygotsky, 1978). This method encourages medical educators to plan wisely and outline the required learning goals and targets imperative for the student’s success. Furthermore, this process assures for greater transparency between the teaching faculty, the content, and the student as the requirements and learning objectives are clearly delineated through the selected material.

The structure of a flipped learning experience requires that the teaching faculty develop an online component for students to interact with. Detailed recommendations provided by the AAMC (2008) and research conducted by Moffett (2014) identify how various technological resources can be incorporated (see Table 2) to enhance the flipped learning environment. Integration of social networking, social media, podcasts, and simulations are a few of the examples teaching faculty may include to encourage students to construct an understanding of the required content. Sharma et al. (2014) emphasized the importance for faculty educators to also interact with the students online prior to the face-to-face activity. This encourages students to become more immersed in the content as they engage with peers and teachers. Finally, to integrate appropriate online content, teaching faculty who develop these learning experiences must keep the learning objectives and goals in mind to assure that students are receiving the necessary material throughout the entire experience. As such, an adequate timeline must be established to allow students enough time to navigate through the online material prior to entering the face-to-face classroom.

When students do enter the face-to-face classroom, teaching faculty must be prepared with advanced content and avoid simply reiterating the information already presented online. This may be a complex case that students must collaboratively solve. Team-based learning is another strategy for engagement in the classroom. This approach incorporates three steps that first, requires students

to complete a pretest independently. During the second step, students collaborate in teams to further conceptualize the material, and finally, at the conclusion of the class, students complete a posttest with their assigned group of peers. This process encompasses the strengths of various learning styles, specifically independent work to collaborative work. An additional strategy teaching faculty could employ is case-based learning (CBL) which encourages students to engage in self-directed learning. CBL integrates a particular and detailed scenario, known as the case which students need to critically evaluate (Gade & Chari, 2013). This type of strategy allows students to work independently or in a group solving exploratory questions.

Technology is a tremendous component of both the online, synchronous portion and the in-class asynchronous teaching. Traditionally, voiced over PowerPoint presentations or short video clips are used, however, there are a number of other online tools to make learning more dynamic (see Table 1).

The above table is not exhaustive of the current available resources applicable for the classroom. As technology and research advances are made, many more applications and online tools will be developed to improve and increase engagement in this blended classroom environment.

FUTURE RESEARCH DIRECTIONS

There is an ongoing need to bridge the gap between educational theory and practice in medical education institutions (Kim, et al., 2014). To accomplish this, additional research should be conducted to further investigate the effectiveness of flipped learning on the development of the student, especially in relation to the acquisition and retention of complex medical content and the implications on patient care. Little research exists regarding the retention and implementation of knowledge as medical students transition to different disciplines, into a residency program, or into their professional career. Flipped learning experiences are multifaceted and it is difficult to pinpoint specifically, which area impacts student learning.

A secondary research area is to investigate the ways in which teaching faculty develop their own professional pedagogical practice. By developing flipped learning experiences, faculty have the potential to also expand their own teaching practice by shifting control away from the “sage on the stage” approach, to instead empower rising physicians. This necessitates supplementary research on teaching faculty’s willingness and acceptance to integrate new technologies and strategies and,

Table 1. Examples of flipped lecture tools

Flipped Lecture Tool	Brief Description
ed.ted.com	Use YouTube to create private videos and embed quiz questions, links, and additional content.
Poll Everywhere	Online application for in-class response system. Can create graphs and real time tallies of who is responding and where misconceptions exist.
Loca Moda	Students can “post” a text message onto an online bulletin board to stimulate discussion.
Google Hangouts	Students can engage in an online, password protected chat room which saves discussions for future reference.
Kahoot	A free, online application that allows for in-class surveys and quizzes.
Articulate Storyline 2	A software program which allows the user to design interactive, online modules with questions, videos, short readings, and simulations.
Wikispaces	Free online tool to allow students and teachers to collaborate and discuss questions and online cases.
TEDTalks and TEDxTalks	Both TEDTalks and TEDxTalks have developed into a vast library of videos that reach a global audience to inspire critical thinking.

in turn, how these new learning experiences are perceived by students.

CONCLUSION

Flipped learning has generated interest and action for change in the education community, from K-12 through to medical education. With the advancements and increased accessibility of technology, students have the opportunity to engage with complex content through various modalities, addressing the diverse learning needs of today's medical student. This curricular process requires that medical educators are well versed in their pedagogical practice in order to design, organize, and implement a flipped learning experience.

KEY TERMS AND DEFINITIONS

Asynchronous e-Learning: The use of online learning resources to facilitate resources without constraints of time or place. Takes the form of discussion boards and blogs.

Flipped Lecture: Students engage with assigned content through online or mobile methods, then attend a face-to-face class to explore the content in more critical ways.

Pedagogy: The art or science of teaching.

Synchronous e-Learning: Online learning that takes place real-time from various remote

locations. Takes the form of videoconferencing and online chat rooms.

Theory of Active Learning: The belief that people learn best from experience and “doing”.

Transactional Distance Learning: Definition of distance education which implies the separation of teachers and learners (Moore, 2007).

Transformative Learning: How learners comprehend, validate, reflect on, and reformulate the meaning of their experience.

Zone of Proximal Development: A concept that informs how learners build on their learning to the ultimate goal of independence.

Integrating Evidence-Based Practice in Athletic Training Through Online Learning

Brittany A. Vorndran

INTRODUCTION

Health care is always changing and as a result the associated health professions must adapt. As challenges persist such as rising health care costs, an aging population and the need to treat increasing numbers of people with chronic health conditions, the field of health care must continue to explore ways to deliver quality care while reducing costs. Like many other health care professions, athletic training has turned to evidence-based practice to assure that athletic trainers are trained to deliver the highest quality of care in the most efficient way to their patients. The transition to integrating evidence-based practice can be challenging and will require a massive diffusion of innovation throughout the field of athletic training.

Athletic trainers (ATs) are defined as “health care professionals who collaborate with physicians. The services provided by ATs comprise prevention, emergency care, clinical diagnosis, therapeutic intervention and rehabilitation of injuries and medical conditions. ATs work under the direction of physicians, as prescribed by state licensure statutes” (Profile of athletic trainers, 2014, para. 1). The profession of athletic training is constantly growing, and athletic trainers can be found in many different settings including high schools, colleges, working with the athletic teams, the military, and workplaces. Despite many employment opportunities, some people in the health care industry are unfamiliar with the responsibilities of the AT and it is apparent that

athletic training as a profession is still lagging behind other allied health professions (Hankemeier & Van Lunen, 2013a).

BACKGROUND

In order to change the perceptions of ATs to the public, the National Athletic Trainers' Association (NATA) is introducing the use of evidence-based practice (EBP) in both the education of new ATs, and in the clinical setting with athletic trainers already working in the field (Hankemeier & Van Lunen, 2013; Hankemeier et al., 2013; McCarty Hankemeier, Walter, Newton, & Van Lunen, 2013; Welch, Van Lunen, & Hankemeier, 2014b). There are many benefits to increasing the use of evidence-based medicine (EBM). One reason that is frequently discussed is improving both the image and recognition of athletic trainers as health care professionals and not personal trainers, physical education teachers, or the people carrying water bottles on the sideline of games. Other benefits to using EBM include improving the care provided to the patients and justifying third party reimbursement (McCarty et al., 2013; Welch et al., 2014a).

Using EBP can be broken down into five steps as shown by Sackett et al. (1996). These steps include: defining clinically relevant questions, searching for the best evidence, critically appraising the evidence, applying the evidence, and evaluating how effective evidence-based medicine was when put to use. While these steps

seem relatively simple when written out, most athletic training clinicians are not presently using EBP in their current treatment practice, but 98% of them were found to believe that it is important for the credibility of the profession (McCarty et al., 2013). Hankemeier et al. (2013b) showed that clinicians had a lower perceived importance score and a lower knowledge score when compared with post-professional educators. ATs who work in an athletic training education program have been more exposed to the notion of EBP and therefore are more knowledgeable regarding it and understand its importance more than individuals that only work in the clinical setting.

Since EBP is very new to the field of athletic training, practicing clinicians that are not recent graduates likely did not learn about EBP in the educational curriculum and would not be familiar with it unless the individual took initiative to learn the process independently. In a study completed by Hankemeier and Van Lunen (2013a) less than 20% of the surveyed clinicians had received any form of EBP training. Based on the information provided in this survey, very few clinicians have been trained to use EBP. These clinicians with no background in using the five steps would need some training in order to be able to effectively integrate EBP into daily clinical practice.

Disseminating knowledge about EBP to ATs is essential in this transition. Continuing education (CE) is an important method for educating athletic training clinicians on what EBP is and how to use. In order for CE to be truly effective, athletic trainers need to understand what modes are best for presenting this information to promote long term knowledge retention and knowledge translation. Popular ways that CE is presented is through online learning, in person lectures, discussions, hands on demonstrations, and mixed mode learning. Studying modes individually for these gains or comparing one type of CE with another will help to advance understanding on how EBP should be presented to maximize an increase in knowledge and use.

Distance education, e-learning, computer mediated, web-based, and online instruction are terms used to describe education delivered through computer-based technologies. Whatever term is chosen, such computer-based technologies are essential components of the preparation and continuing education of health professionals. One of the most frequently used modes of CE, particularly for learning EBP, is online learning. Web-based learning has become very popular due to its flexibility and ease. This type of learning can be done from anywhere and completed at the convenience of the individual taking the course (Militello, Gance-Cleveland, Aldrich, & Kamal, 2014).

Allied health care tends to use three models of online learning and instruction: blended learning, online learning, and continuing education (Stewart & Wright, 2004). Blended learning includes both face to face and online learning and instruction. Online learning is learning and instruction that is completely web-based. Continuing education for health professionals is offered in both blended and online formats. In fact, most health-related disciplines are using a combination of online and face-to-face learning in their programs.

From a theoretical standpoint, characteristics of an effective online learning experience have been outlined. Reeves and Reeves (2008) provided 10 dimensions to be considered when designing, implementing and evaluating an online class in health and social work. The model they described for health and social work education included 10 dimensions of interactive teaching and learning:

1. Pedagogical philosophy;
2. Learning theory;
3. Goal orientation;
4. Task orientation;
5. Source of motivation;
6. Teacher role;
7. Metacognitive support;
8. Collaborative learning support;
9. Cultural sensitivity; and
10. Structural flexibility.

In the discussion of developing online learning formats, best practices often discussed include attention to instructor and student interaction, application of active learning techniques, providing prompt feedback, and attending to diverse ways of learning. While the aforementioned guidelines make sense, they have not been vetted through research. This brings us to the next questions of whether web-based instruction can be as effective as face-to-face education. The answer is that we really do not know how effective face-to-face education is, because comprehensive assessment is rarely conducted of student learning for specific courses. Many factors play a role (i.e., faculty training and course design) in the effectiveness of any course. Most health professionals rely heavily on technology in their practice and thus, it seems appropriate for technology to play a role in the education of future health professionals. In fact, Hollis and Madill state (2006), "Evidence suggests that blending combinations of technologies with computer mediated learning enhances interaction and could address the higher order learning needs of professional programs such as occupational therapy" (p.61).

Through a review of research focused on computer-enhanced classroom-based teaching, online courses, online degree programs, and online continuing professional education, Hollis and Madill (2006) recommended that both online and face-to-face teaching and learning opportunities accommodate all types of students and faculty. Hollis and Madill (2006) emphasized the use of multiple technologies to enhance interaction between students, and between students and instructors. However, to optimize the effectiveness of online learning, they suggested appropriate preparation and support is required for both students and faculty. Again, these suggestions make sense, but also must be vetted through research designed to assess effective online learning experiences.

How is blended and online learning and education being used in health professions? Konin (2004) discussed how to enhance clinical education, like athletic training, through the use of web-

based programs. Like most health professionals, education and training includes some type of fieldwork, or internship placement. Information and assessments for clinical instructors can be delivered electronically through an online course management system such as Blackboard. Face-to-face class formats can be enriched through the availability of a multitude of supplemental online materials.

A study was completed with nursing clinical preceptors who worked with undergraduate nursing students. In this study the preceptors took part in a series of online CE course objectives. These objectives were geared toward the roles and expectations of a clinical preceptor. The results showed that there was a statistically significant gain of knowledge between the pre-test and post-test, showing that knowledge was gained from online learning (Zahner, Tipple, Rather, & Schendzielos, 2009). While this study showed that online learning can increase knowledge, it did not compare online learning with traditional learning methods such as live lectures.

There is research that has been done that compares online learning with traditional live lectures. One study completed by Phillips (2015) investigated the effects of teaching a lesson online versus the traditional in person lecture class. This study was completed using a class in a pharmacy program. Students were randomly assigned to either the control group of traditional lectures, or the experimental group of active online learning. The experimental group performed higher on a multiple choice quiz given immediately after the lesson, but there was no significant difference on the final exam scores between groups. The experimental group did express that the online class was enjoyable and felt that it should be used in conjunction with traditional lectures, but should not replace lectures altogether.

Online learning and instruction is also essential to the continuing education of health-related professionals. Williams (2006) conducted a meta-analysis of 25 studies assessing achievement in distance education in allied health and found that

distance education is as effective as face-to-face instruction. Student achievement outcomes were positively correlated with work experience and professional knowledge. Outcomes were also better for distance education experiences that included multiple learning and instructional strategies including, but not limited to, interaction and introspection.

Continuing education for ATs is offered in many different forms including taking college courses, publishing papers, presenting at conferences, attending in person meetings or education seminars, and online learning (Board of Certification, 2016). Studies have shown that online CE is frequently used because of the cost effectiveness and the ease of completing it individually (Armstrong & Weidner, 2011). December 2015 was the first reporting period that required athletic trainers to complete CE in an evidence-based practice category. During this period, ATs could choose from many different online options. These were typically formatted with a lesson that ended in a quiz to test knowledge. Passing the quiz was necessary for receiving the continuing education units. Because this reporting period ended so recently, there is no research yet available on its effectiveness. However, a study was completed by Welch et al. (2014a) that looked at the web-based modules pertaining to EBP.

In this study, there was an experimental group that had access to the continuing education learning modules, and a control group that did not. Both groups were given a pretest and a posttest to assess knowledge. The experimental group did significantly better than both their own pretest and the control group's scores on the pretest and the posttest. Learning was achieved in this study, but only short term knowledge gain was investigated. Whether this knowledge was retained in the long term from the online learning modules has not yet been concluded.

The experimental group in the previous study was also interviewed on their perceptions of evidence-based practice following the interven-

tion. Overall, the response was positive with the individuals all feeling that they had learned from the modules and had a better understanding of the concepts of EBP and how to use it (Welch et al., 2014b). However, the clinicians reported that the modules did not cause a change in clinical practice and that although they learned they did not change the way they made treatment decisions. Other qualitative studies have also been done regarding the attitudes toward EBP education. A topic that was emphasized was the need for constant repetition and increased exposure to evidence-based practice. These participants felt that the more exposure one has to EBP, the more comfortable they will become with it and the more likely they will become to use it (Welch et al., 2014c). A recent study by Keeley et al. (2016) found that participants felt that EBP was important, but overall they had not used EBP concepts at all in the eight weeks prior to completing the survey. The importance of EBP and short-term knowledge gain seem to be occurring, but there is still a gap between putting that knowledge to practice.

The reason that EBP is such a hot topic in the world of health care is to improve clinical outcomes, decrease cost, and increase patient satisfaction. To effectively implement EBP into athletic training, the athletic trainers must be using what they are learning through CE (Hankemeir & Van Lunen, 2013; Welch et al., 2014a; Welch et al., 2014b). More research needs to be done that helps to understand whether online, traditional, or a mixed mode of CE is most effective for knowledge gain and clinical use. Research that measures how well and individual is learning and whether that person is retaining the knowledge will help to make adjustments to the current situation regarding EBP. Comparing different ways of receiving the knowledge for effectiveness will also help to promote meaningful learning and knowledge translation. December of 2015 is the first time that ATs needed to report CEUs from an EBP category. It is likely that this will not be perfect on the first attempt. Continuing to understand the best ways

to increase the translation of knowledge in athletic training will help the profession to successfully incorporate EBP into daily practice.

Some studies have been completed that investigate the notion of using a mixed mode method of learning. This type of CE would include different methods of learning such as combining web-based learning with an in-person discussion, or hands on demonstration that compliments what was previously learned (Militello et al., 2014). The idea that mixing a passive lecture whether online or in person with an active discussion or demonstration works well with the idea that individuals learn differently. Furthermore, reinforcing a topic often promotes long term retention, comprehension, and may increase the chance that it will be implemented into clinical use (Schreiber, Perry, Downey, & Williamson, 2013; Zahner, et al., 2009).

A particular study that utilized a more comprehensive and multifaceted approach was completed by Schreiber et al. (2013). This study used a course that was geared for physical therapist (PTs) and met on three separate occasions in conjunction with an online community used to foster discussion. During the in-person meetings, there were lectures, hands on demonstrations, and time to talk about successes and barriers to implementing the clinical change learned. In the final session, all PTs were required to discuss how they had already used what was learned in the previous courses in the clinical setting with patients. They also needed to describe an EBP activity that they had undertaken in the clinical setting. This study showed that the participants enjoyed this mixed methods learning and showed improvement in knowledge and practice behaviors such as supporting colleagues' use of interventions and tests and measures that were related to the course content.

Studies are showing that multifaceted learning increases knowledge and the translation of knowledge into clinical practice (Schreiber et al., 2013; Zahner et al., 2009). In order for change to truly occur in the field of athletic training more research needs to be completed that investigates how effective the current CE learning methods are.

Short term knowledge gain is not enough to truly make a change. Whether long term knowledge gain is occurring is also important. If an individual is forgetting the course content immediately following the course then the information is not being relayed effectively (Phillips, 2015). This information must be something that the AT can comprehend and remember after a period of time. Even more importantly, however, is the idea of translating this knowledge in to clinical practice.

FUTURE RESEARCH DIRECTIONS

As previously mentioned, one of the benefits to online continuing education is that it can be completed at the convenience of the individual. This however, can also be a drawback. Each reporting period for continuing education is two years (Board of Certification, 2016). During that two-year period, athletic trainers can complete all of the CEUs at any time. This means that the CEUs can be completed two years early, or one day before the reporting period ends. It may be more beneficial to the profession if the EBP continuing education had benchmarks throughout the two year period that needed to be met. This would allow for continual exposure to the concepts and the idea of EBP throughout the reporting period, without it all being crammed into a few days or weeks and then forgotten about. Online learning would easily allow for this to happen with lessons and quizzes having due dates throughout the reporting period.

A more interactive online learning experience may be beneficial. Most of the online continuing education to this point includes a lesson followed by a quiz at the end (Welch et al., 2014a). This allows for an individual to pay minimal attention to the lecture itself and only focus on the quiz at the end. However, if there were checkpoints throughout the lecture where the individual had to answer a multiple choice question, or fill in the blank there would be more attention paid to the lecture. This may also increase interest in the topic. The quizzes that are used at the end

should also be evaluating a true understanding of the topics that are being presented and should be challenging enough that individuals are proving that they understand the information that was presented. Online continuing education is received positively by athletic trainers due to the cost and convenience, so making it effective is important to increasing the use of EBP (Armstrong, 2011).

Continuing education in EBP was provided through online courses, at sessions at the national and regional conferences, and at in-person seminars throughout the country. The way an individual athletic trainer received the CEUs was a personal decision. It is frequently shown that expense and convenience of continuing education play a very significant role in why it is selected (Cuppitt, 2001). Athletic trainers that work in a traditional setting such as a high school or college and are working unpredictable hours and weekends may be more inclined to complete the CEUs online due to convenience. Additionally, many ATs are paying for the continuing education independently and therefore will pick the most cost effective option. Unlike students in an athletic training program who will receive EBP information in a formal didactic setting that is constantly reiterated, certified ATs are only receiving this information when it is presented in the CE and through an additional education sought out individually (McCarty et al., 2013). Certified ATs may take longer to truly feel comfortable with the concept of EBP and may need additional reinforcement beyond the CE to promote a behavior change.

One of the major recurring themes relating to barriers of implementing EBM is that ATs are not comfortable with the process and therefore will not use it (Hankemeier & Van Lunen, 2013a). Many of the practicing athletic trainers were not taught how to use the process of EBP while in school resulting in not being comfortable reading scholarly articles and deciding what should be considered when making treatment decisions. This is one of the reasons that EBP is now in all athletic training education curriculums, but this does not help ATs that are already practicing. The

other major complaint is that the ATs working in many of the various clinical settings do not have time to go through the whole process of using EBP, particularly reading through lengthy articles to help with treatment decisions (McCarty et al., 2013; Welch, 2014a). Truly analyzing a peer-reviewed article to determine its value can be very time consuming. In a clinical environment where athletes and other patients may constantly be around and needing attention, it can be difficult to take the time to read articles and determine whether it has any relevant information that can be applied to the particular situation. Due to the time consuming nature, many ATs feel it is easier to just do what is comfortable or what has always been done because it allows patients to be seen and taken care of in a timelier manner (McCarty et al., 2013; Welch et al., 2014a). One study indicated that ATs stated that if the information in the articles were in a quicker, more streamlined medium there was a higher chance of reading it and utilizing it because it would be less time consuming (Welch et al., 2014a).

A possible way to help ATs understand scholarly articles is through the use of an online database. Since ATs understandably would be challenged with reading scholarly articles, it seems like asking researchers to provide EBP application summaries of their articles to an online open access database for ATs would be a good solution. The *Journal of Athletic Training* (JAT) is currently available to all members of the NATA. This journal comes out quarterly with monthly supplements and is available online. Currently ATs have access to the abstract, full text, and a PDF version. This is a great asset to ATs, but a frequent complaint is that using EBP and looking through research articles is too time consuming for the fast paced unpredictable nature of the job (McCarty et al., 2013). Since this journal is published for athletic trainers and typically by athletic trainers it would be beneficial if each author were asked to provide 3-5 bullet points that were directly related to applying the information in the article to practice. These bullet points could be added to the end of

the abstract and would help to streamline the information in the article which has been requested by practicing ATs (Welch et al., 2014a). The abstract and the EBP bullet points would allow ATs to quickly look to see whether an article is worth taking the time reading through and may allow clinical ATs to put more evidence into practice without spending valuable time reading through something to end up not using it.

If this were to become successful and widely used the NATA could also begin to provide research from other journals outside of JAT. While the JAT is a great source for information for athletic trainers, there are many other journals that also produce useful information from other allied health professions. It could be beneficial for ATs to have exposure to research that is being done in other field such as nursing and physical therapy. This exposure would broaden the knowledge of ATs and could increase interprofessional collaboration. Finding a way for ATs to be able to quickly determine whether an article is worth reading could be one way to increase the use of EBP and using bullet points that are provided with the abstract is one possible solution.

CONCLUSION

A major transition is occurring to achieve the implementation of EBP throughout the field of AT. In December of 2015, athletic training professionals were required to report ten of their fifty CEUs in an EBP category. This was the first time that athletic trainers needed a portion of CEUs to come from an EBP section. This means that all athletic trainers who would like to maintain certification have recently taken courses either online or in person that teach about EBP. The goal is that this will familiarize all ATs with EBP in hopes that it will begin to be used more. However, since this is the first reporting period that required the EBP category, there is little known about how effective adding CEUs in the field of EBP will be and whether knowledge will be gained and translated

into practice. Changing the way online continuing education is presented and completed by ATs may increase comprehension and understanding of EBP. This understanding may lead to using it in clinical practice. Having benchmark requirements for completing the CEUs throughout the two year period could lead to more frequent exposure to all ATs and may increase the understanding. This checkpoint process would prevent ATs from completing all CE at the beginning or end of the reporting period, and would instead spread it out throughout the two years allowing for increased exposure. One major complaint for using EBP in the clinic is a lack of comfort with how to use it (Hankemeier & Van Lunen, 2013a). Increasing frequency of exposure may help to make clinicians more comfortable with how to use EBP causing a change in practice. While there will no doubt be challenges associated with the implementation of EBP in athletic training, the use of online learning mentioned in this chapter may ease the transition for athletic trainers, managers, and organizations.

KEY TERMS AND DEFINITIONS

Allied Health: The segment of the workforce that delivers services involving the identification, evaluation and prevention of diseases and disorders; dietary and nutrition services; and rehabilitation and health systems management.

Athletic Trainers (ATs): Health care professionals who collaborate with physicians to provide prevention, emergency care, clinical diagnosis, therapeutic intervention and rehabilitation of injuries and medical conditions (Profile of athletic trainers, 2014, para. 1).

Continuing Education: Education provided for adults after they have left the formal education system, consisting typically of short or part-time courses.

Evidence-Based Practice: Evidence based medicine is the conscientious, explicit, and ju-

icious use of current best evidence in making decisions about the care of individual patients (Sackett et al., 1996).

Knowledge Translation: A dynamic and iterative process that includes synthesis, dissemination, exchange and ethically-sound application of knowledge to improve the health of patients, provide more effective health services and products, and strengthen the health care system (Graham et al., 2006).

National Athletic Trainers' Association (NATA): A professional membership association serving certified athletic trainers and others who support the athletic training profession in the United States.

Transitions: Change processes that involve a beginning, middle, and an end.

M

Integrating Web-Based Technologies into the Education and Training of Health Professionals

Michelle Lee D'Abundo
Seton Hall University USA

Cara Sidman
Arizona State University, USA

INTRODUCTION

With rising health care costs and the need to treat more and more people with chronic health conditions, many people wonder how healthcare can be advanced in America. Along with healthcare reform, education and training will play a significant role in meeting increased demands for health professionals. In this chapter, exploration of how online learning and instruction can be used to meet the educational needs for the healthcare industry is detailed.

Distance education, e-learning, computer mediated, web-based, and online instruction are terms used to describe education delivered through computer-based technologies. Whatever term is chosen, such computer-based technologies are essential components of the preparation and continuing education of health professionals. For many health professions, formal education, as well as continuing education, includes some type of web-based learning, with some programs completely online.

The American Journal of Health Promotion (2009) defined health promotion as:

Health Promotion is the art and science of helping people discover the synergies between their core passions and optimal health, enhancing their motivation to strive for optimal health, and supporting them in changing their lifestyle to move toward a state of optimal health. Optimal health is

a dynamic balance of physical, emotional, social, spiritual, and intellectual health. Lifestyle change can be facilitated through a combination of learning experiences that enhance awareness, increase motivation, and build skills and, most important, through the creation of opportunities that open access to environments that make positive health practices the easiest choice.

In this chapter, health promotion refers to all education and programming relating to health that is intended to promote positive health outcomes. Many health promotion interventions and programs are conducted online. In fact, the term e-health has been created to describe web-based health promotion initiatives. Health care professionals and health educators are using online instruction to teach patients. Higher education courses that promote lifelong wellness, including physical activity-based courses, are also using online learning formats.

The objectives of this chapter are: 1) to understand the benefits, quality indicators and use of online learning and instruction in health; 2) to discuss whether online learning and instruction is appropriate for training health professionals and for the delivery of health promotion; 3) to review an example of how blended and online instruction can be used for health promotion in higher education; 4) to discuss future trends for online learning and instruction in health.

DOI: 10.4018/978-1-5225-2255-3.ch506

BACKGROUND

In 2013, the Bureau of Labor Statistics reported there were more than 15.8 million jobs in the combined healthcare industries (Torpey, 2014). It is projected that over 4 million jobs will be added between 2012 and 2022, which is more than any other industry (Torpey, 2014). As the largest industry, the demands for preparation and continuing education of health-related professions comprise a significant percentage of adult education conducted in the United States.

Health care professionals are in demand throughout America, but are particularly needed in Health Professional Shortage Areas (HPSAs). According to the U.S. Department of Health and Human Services (2016), 8,200 practitioners are required to meet the need for primary care providers in HPSAs. In order to meet the demands for qualified health care professionals in America, institutions of higher education have sought cost efficient and effective methods of preparing and training health care providers. One way to address the high demand for education, especially for areas that do not have institutions of higher learning, is to begin to offer and expand distance education opportunities. The current use and continued expansion of online learning and instruction in higher education has caused health-related disciplines (and most other disciplines) to ask some difficult questions, which will be explored in this chapter.

SIGNIFICANT QUESTIONS AND ISSUES IN ONLINE LEARNING AND INSTRUCTION IN HEALTH

The health and wellness of individuals, communities, and society are largely dependent on health care providers and health promotion. Consequently, much discussion and debate has occurred as the delivery of adult education and training has evolved to include web-based learning and instruction in the field of health. Some of the significant questions and issues in the discussion about online learning and instruction include the

benefits, quality indicators, and the current use in the field of health.

One of most often asked questions is, “what are the benefits of online learning and instruction?” For potential students who are employed full-time, on active-duty in the military, have family obligations, or are geographically remote, online programs may be the only option for completing their education. According to Chaney et al. (2009), distance education programs benefit students and the university at large. For students, graduation time can be decreased through easier access to courses. Chaney believes distance education diversifies student populations as courses are accessible from any part of the country or world. For the university, strains on the built environment are resolved as no space is needed on campus. Costs are also reduced as all types of printing are eliminated when course materials and assessments are conducted online.

Online learning and instruction can also benefit the environment. Many campuses have struggled to resolve parking and air quality issues. Distance education reduces travel to and from campus, which significantly reduces student and faculty costs for travel, and the inevitable environmental effects associated with auto admissions.

Another question asked is, “what are the quality indicators of online learning and instruction for health-related professional education?” Like all disciplines, health professionals, faculty, and students have their opinions about what contributes to effective web-based learning and instruction. Reeves and Reeves (2008) provided 10 dimensions that should be considered during the instructional design, implementation and evaluation of online courses in health and social work. The model they describe for health and social work education includes 10 dimensions of interactive teaching and learning:

1. Pedagogical philosophy;
2. Learning theory;
3. Goal orientation;
4. Task orientation;

5. Source of motivation;
6. Teacher role;
7. Metacognitive support;
8. Collaborative learning support;
9. Cultural sensitivity; and
10. Structural flexibility.

While the description of these dimensions is beyond the scope of this chapter, overall they emphasize important pedagogical practices translated from the face-to-face to the online environment.

Chaney et al. (2007) described some similar quality indicators of distance education, with some additional ones specifically related to technology. These researchers agree with the importance of interaction, especially between the students and teacher. Other best practices include incorporating the use of active learning techniques, providing prompt feedback, and respecting diverse ways of learning. It is essential for any distance education program to correlate to the mission of the institution, implements the use of appropriate, and reliable multimedia tools, all while providing sufficient student and faculty support and resources. Instructors designing these courses need to provide a clear course structure and means for program evaluation and assessment so improvements can be made.

How is online learning and instruction used in the training of health professionals? Allied health care is using three models of e-learning: blended learning, online learning, and continuing education (Stewart & Wright, 2004). Blended learning includes both face to face and online learning and instruction. Online learning is learning and instruction that is completely web-based. Continuing education for health professionals is offered in both blended and online formats. In fact, most health-related disciplines are using a combination of online and face-to-face learning in their programs.

Perhaps the most salient question to ask is, “Is web-based instruction an effective mode of educating health professionals?” While this question is still in need of additional research evidence to

provide data-based answers, and many factors play a role (i.e., faculty training and course design), it certainly can be. Most health professionals rely heavily on technology in their practice and thus, it seems appropriate for technology to play a role in the education of future health professionals. In fact, Hollis and Madill stated (2006),

Evidence suggests that blending combinations of technologies with computer mediated learning enhances interaction and could address the higher order learning needs of professional programs such as occupational therapy. (p.61)

Through a review of research focused on computer-enhanced classroom-based teaching, online courses, online degree programs, and on-line continuing professional education, Hollis and Madill (2006) recommended that both online and face-to-face teaching and learning opportunities accommodate all types of students and faculty. Hollis and Madill (2006) emphasize the use of multiple technologies to enhance interaction between students, and between students and instructors. However, to optimize the effectiveness of online learning, they believe appropriate preparation and support is required for both students and faculty.

How is blended and online learning and education being used in health professions? Konin (2004) discussed how to enhance clinical education, like Athletic Training, through the use of web-based programs. Like most health professionals, education and training includes some type of fieldwork, or internship placement. Information and assessments for clinical instructors can be delivered electronically through an online course management system such as Blackboard. Face-to-face class formats can be enriched through the availability of a multitude of supplemental online materials. McLeod and Barbara (2005) reported, “The use of online chat rooms was seen to be beneficial to encouraging peer support while on fieldwork for allied health students” (p.276).

Web-based education has also been used to teach medical students. A web-based self-study

was developed to teach medical students how to help smokers quit and how to prevent others from starting to smoke. The curriculum helped medical students develop effective counseling skills in the prevention and treatment of smoking (Pederson, Blumenthal, Dever & McGrady, 2006). In another study, third- and fourth-year medical students completing a web-based women's health curriculum valued learning women's health, preferred this self-directed learning over lecture, scored highly on knowledge tests, and were involved in more high-level discussions of women's health with faculty (Zebrack et al., 2005).

Online learning and instruction is also essential to the continuing education of health-related professionals. Williams (2006) conducted a meta-analysis of 25 studies assessing achievement in distance education in allied health and found that distance education is as effective as face-to-face instruction. Student achievement outcomes were positively correlated with work experience and professional knowledge. Outcomes were also better for distance education experiences that included multiple learning and instructional strategies including, but not limited to, interaction and introspection.

WEB-BASED HEALTH PROMOTION

Researchers have examined online health promotion and found them to be effective methods of information delivery (Parlov, Cowdery & Hoerauf, 2004; Shegog et al., 2005). Wantland et al. (2006) conducted a meta-analysis of effects of patient knowledge and behavioral change outcomes in web-based and non-web-based interventions. In 16 of 17 web-based interventions reviewed, participants showed improved knowledge and behavioral outcomes. D'Abundo, Fiala, and Mariano (2010) found that an online learning module was an effective way to deliver information about smoking to college students in a general education fitness and wellness course. Some advantages of computer-based health promotion activities in-

clude individual tailoring, consistency of content, the incorporation of media, and availability of the program when a person is ready to make a change.

In order to meet the health promotion goals of many universities and colleges, university basic study curriculums include required hours in courses that promote life-long wellness. Many such courses are delivered in face-to-face formats and require participation in some type of physical activity. Like issues involved in the preparation of future health professionals, there are obstacles encountered in accommodating the diverse needs of learners in the university setting. The option of web-based delivery of such courses may help meet the demands of an ever-expanding student population.

RECOMMENDATIONS

For the practitioners and faculty that design, implement and evaluate training of future health professionals and health promotion interventions and programs, it may be difficult to envision how to develop blended and online courses/programs from existing traditional curriculums. There may also be concerns about how to ensure that objectives are being met in blended and online formats. The following are suggestions about developing blended and online instruction focused on health promotion in higher education. The information may be applied to the training of future health professionals as well health promotion activities outside of education.

1. **Start with Blended Courses Before Moving to Completely Online Formats:** For some health professionals and health faculty, it is difficult to decide how to adapt existing educational materials, activities and programs to web-based delivery. For both blended classrooms and completely online learning environments, there are a numerous online resources that are available for educational purposes. For example, PBS provides

much of their health-related programming on their website and includes educational materials for discussing the content. Bennett (2005) described the potential for using The Multimedia Educational Resource for Learning and Online Teaching (MERLOT) as an online resource linked to thousands of learning objects. Resources available include online learning materials, peer reviews, learning assignments, and user comments, all organized by discipline. Instructional technology consultants are also available to assist with the development of online learning materials and curriculums.

2. **When Moving Completely Online Go Beyond Content and Strive to Increase Interaction!** One criticism of online learning and instruction is that it limits both student-to-student and instructor-to-student interaction. Those of us that teach both online and face-to-face formats realize that interaction largely depends on the facilitation of class and the members of the class itself. In order to continue to raise awareness about web-based education, it is important to educate practitioners, students, and the public about the potential of online education.

One way to alleviate some of the concern about the lack of instructor and student interaction in online classes is to design strategies to promote interaction and build community among student and participants. Stow (2005) stated that in online courses, activities should include multiple types of interaction. The author recommends that the instructor communicate with the students in a timely manner. Stow suggested that methods like chat rooms, discussion, and feedback allow the students to become actively engaged in order to decrease the transactional distance.

One way to increase student interaction and build community in blended and online course formats is the establishment of "Course Buddies." The objective of using "Course Buddies" is to build community in blended and online courses

and in health promotion programs delivered in a web-based format. To begin the "Course Buddy" selection, instructors can ask students to post introductions that include three things that most people do not know about them and include a picture. The next step is to have students review each others' introductions and find three people that they have things in common with or they want to get to know better. Then instruct students to e-mail potential "Course Buddies" to exchange contact information or just communicate by using e-mail. The process of finding "Course Buddies" in itself helps build community and enables students to learn more about each other. Once "Course Buddies" are established, students can discuss activities, study for exams or work on assignments.

FUTURE TRENDS

The future for online learning and instruction in health seems promising as we strive to meet the demands of an ever-changing health care system with accessible training and continuing education opportunities. However, to further facilitate successful use of online delivery methods to train health professionals and to promote health, data-based research describing and analyzing its effectiveness is essential. Advocacy on the part of professionals in health-related disciplines is also critical for web-based education methods to be embraced. Part of such advocacy includes increasing awareness of the online opportunities that already exist and exploring the potential of alternate computer based methods of delivery. Those interested in advocating for online education may want to join The United States Distance Learning Association.

In order for online learning to continue to grow and become embraced, myths associated with this mode of instruction need to be dispelled. While it is undoubtedly serving a need, and the technologies available to interact with learners from a distance continue to evolve, professionals and educators with substantial reservations regarding its role

in teaching and learning remain. It is recognized that online learning is not for everyone, and it may not be the best method for teaching certain types of curriculum, it is certainly effective if taught based on sound instructional design principles and well trained instructors. A successful future that optimizes the use of online teaching and learning depends on the collaboration and communication among professionals regarding the most effective ways to meet learning objectives. Once those are established, technology use can be designed around those objectives, and not vice versa.

Another trend in online education is peer review. As online learning and instruction continues to expand in health-related disciplines, much discussion focuses on how to ensure the quality of web-based programming. Peer review has been suggested as a way to review and improve online course delivery as well as health promotion efforts. Quality Matters © (QM) (Quality Matters, 2016) is a peer-review process designed to certify the quality of online courses. The Quality Matters process uses a rubric to review eight broad standards in blended and online courses that include: learning objectives, assessment and measurement, resources and materials, learner engagement, course technology, learner support and accessibility. Many programs throughout the country have created their own versions of peer review or “online observations” to assess the quality of web-based curriculums.

CONCLUSION

As described in this chapter, online learning and instruction have become important components of formal and continuing education for health professionals and in health promotion programs. Curriculums that have previously been thought to be inappropriate for web-based delivery are now being offered online. Innovations in online learning and instruction have improved delivery of web-based education and have provided educational opportunities for many that were “unreach-

able” by traditional classrooms. As web-based educational opportunities continue to expand, it is our hope that more health professionals and the general public will learn about the efficacy and possibilities of online learning and instruction.

KEY TERMS AND DEFINITIONS

Blended Learning and Instruction: Includes both face- to-face and online learning and instruction.

Course Buddies: An ice-breaker or introduction strategy used to build community in blended and online courses and in health promotion programs.

E-Health: Health promotion initiatives delivered online.

Face-To-Face Learning and Instruction: Course activities and instruction occur in the traditional classroom without the use of online learning and instruction.

Health Promotion: Refers to all education and programming relating to health that is intended to promote positive health outcomes.

Health-Related Professions: Professions that delivery medical care and health promotion including but not limited to nursing, occupational therapy, athletic training, respiratory therapy, physicians, physician assistants, social workers, and health educators.

Online Learning and Instruction: Learning and instruction that is completely web-based.

Interactivity in Distance Education and Computer–Aided Learning, With Medical Education Examples

M**D. John Doyle***Cleveland Clinic, USA***Patrick J. Fahy***Athabasca University, Canada*

INTRODUCTION

Webster's Revised Unabridged Dictionary defines interaction as: 1. intermediate action, 2. mutual or reciprocal action or influence; as, the interaction of the heart and lungs on each other. The *Oxford English Dictionary* defines interactivity as reciprocally active, allowing a two-way flow of information between source and user, responding to the user's input. This is the view advocated by many observers (Wagner, 1994; Wagner, 1997; Anderson, 2003). Notes Anderson: "Simply stated, interactions are reciprocal events that require at least two objects and two actions. Interactions occur when these objects and events mutually influence one another" (p. 8). The concept of "interaction" in education and training varies with subject domain (e.g., philosophy versus physics), with format (e.g., conventional versus distance education) and with other factors. Although the term is frequently overused and poorly understood, the notion of interactivity remains important and useful, and is especially topical given the availability of technologies designed to support advanced interactivity.

BACKGROUND

In his book *The Art of Interactive Design*, Crawford (2002) discusses the notion of interactivity in terms of a conversation: "a cyclic process in which two

actors alternately listen, think, and speak," and notes that the "quality of the interaction depends on the quality of each of the subtasks (listening, thinking, and speaking)." This model of interactivity avoids some of the pitfalls associated with some definitions offered in the past.

As noted above, educators place considerable importance on interactivity in learning (Anderson & Garrison, 1995; Fahy, 2005; Garrison & Cleveland-Innes, 2005; Lapadat 2007, Faghihi et al., 2016). Well-designed interactivity can help capture the learner's interest, has the potential to speed learning, and allows for continuous assessment of the degree to which the material is mastered. Technology (at least theoretically) can allow for high-quality interactivity by providing for frequent and relevant user feedback, by recognizing when students misunderstand a concept, and by providing aids such as animations or graphs that vary with user input. However, badly designed interactivity can also impede student progress, suppressing, or making more difficult, program flexibility and learner independence (Burbules & Callister, 2000; Faghihi et al., 2016) (*vide infra*).

The importance of interactivity in learning is illustrated by the fact that a number of journals address this topic. For instance, the *Journal of Interactive Learning Research* (JILR) publishes manuscripts dealing with "the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments," including such varied

DOI: 10.4018/978-1-5225-2255-3.ch507

topics as “authoring systems, cognitive tools for learning computer-assisted language learning, computer-based assessment systems, computer-based training, computer-mediated communications, computer-supported collaborative learning, distributed learning environments, electronic performance support systems, interactive learning environments, interactive multimedia systems, interactive simulations and games, intelligent agents on the Internet, intelligent tutoring systems, microworlds, virtual reality based learning systems,” and anything else related to these.

In this review, we will discuss interaction in distance education and training, with an emphasis on medical education. Since educational technologies are often used to support interactivity, an important theme will be how technologies can support or impede interaction.

Interaction in Publication

Few would argue that published documents form a very important component in education. Stevan Harnard (1992) has emphasized that electronic publication provides a dimension of interactivity in document publication that is radically new. While online journals are still in evolution, and the form they will ultimately take – combining reader access with content credibility and publisher concerns – is still being determined, there can be little doubt that online journals are here to stay.

Interaction in Distance Education

One simple definition of “distance education” is that it is the delivery of instruction that does not require the student to be present in the same location as the instructor. What then is “interaction” in distance education? We suggest that it is a generic or broad term, covering all manner of notions of amplification, appraisal, clarification, commentary, communication, exploration, feedback, involvement and participation in the context of an educational exercise.

In more concrete terms, interactivity may be based on, or supported by, communication technologies such as the telephone, e-mail, instant messaging, or computer conferencing, as well technologies such as computer-based simulation. As such, it may be hard to define the concept of interaction precisely. Regardless, the notion of interaction should become clearer as the reader reads on.

Finally, it should be noted that although many individuals (e.g., Gilbert & Moore, 1998) use the terms “interaction” and “interactivity” interchangeably, some authors draw a distinction between the two. For example, Wagner (1994, 1997) defines “interaction” in terms of an interplay of behaviors in which individuals and groups influence each other, while “interactivity” is defined in terms of real-time characteristics of technological systems.

Importance of Interaction in Distance Education

Moore & Kearsley (1996) describe three types of interaction within distance education. McIsaac & Gunawardena (1996) add a fourth type, which takes into account the interaction that occurs when a learner must use educational technologies as part of the learning process. In these descriptions, students in a distance education “learning environment” are thus said to interact variously with the instructor, the content, the technology, and with other students.

In addition to these four forms of interaction, further distinctions must be made between instantaneous (“real time”, “synchronous”) and delayed (“asynchronous”) interaction, as well as between “same-place” and “different-place” interaction. Generally speaking, delayed and different-place interaction offer the student more flexibility and opportunities for thought and reflection, while immediate and same-place interaction, some would say, may allow for a greater sense of spontaneity, impulsiveness and even exhilaration.

With conventional classroom-based teaching, the focus is predominantly on student-teacher interaction, with student-content interaction also taking place, especially when out-of-classroom reading takes place. In the distance education setting, with the heavy use of self-study materials, the focus is usually on student-content interaction, with other forms of interaction occurring to varying degrees. Interaction with technology is also frequently important. Finally, recent research in collaborative and cooperative learning environments, especially those involving computer networks, has led to new insights into the nature of student-student (or more generally, peer-peer) interaction.

Note also that the above four-pronged approach to interactivity in education is not the only available model. In some educational domains alternate models may prove to be useful. For instance, we

have developed a rather different six-category approach to interaction, outlined in Table 1, which we believe works well to help explain the notion of interaction in the realm of distance education, using examples from medical education.

Learners and instructors will have preferences regarding interactivity, and some forms of education will rely on some forms of interactivity more than others. Regardless, the wise use of interactivity will help “engage” students and help ensure an enduring learning experience - learning enhanced by the potential individualization of the experience (Simonson et al., 2009).

Interactivity as a Driver of Change in Education Delivery

Interactivity requires a fundamental change in the manner in which education is delivered. Tapscott

Table 1. Types of interactivity in teaching and education, with examples focusing on medical education

[1] Person-to-person (student / teacher) interaction with both persons in direct verbal communication (“same place interaction”)
• Formal classroom or auditorium teaching (such as a question and answer period at the end of a lecture)
• Informal hallway or bedside discussions
[2] Person-to-person interaction (student / teacher) using remote communication technology (“different place interaction”)
• Telephone and audio conferencing
• Writing (paper, e-mail)
• Video conferencing
• Telemedicine (e.g., clinical discussion centering around a radiographic image)
[3] Paper-based interactivity [can also be “morphed” to a computer model]
• Interactive paper scenarios (If X is true then go to page Y otherwise go to page Z)
• Example 1: Patient with chest pain presents to the ER where Y = “admit patient to hospital”
• Example 2: Patient with abdominal pain presents to the ER where Y = “operate on patient [laparotomy]”
[4] Paper-based interactivity based on “developer pen” technology [can also be morphed to a computer model]
• Developer pen technology allows the student to see the result of a study or laboratory test once it has been “ordered”; based on the result of the selected investigation the student selects other clinical options (e.g., asks more questions, attempts to elicit a particular clinical finding, orders another test)
[5] Computer-based interactivity not using the World Wide Web. This usually involves using programming languages such as C++ or various older authoring platforms.
[6] Web-based interactivity. This usually involves using programming languages such as JavaScript or authoring platforms with Web support.

Note: further distinctions can to be made between immediate (“synchronous”, “real time”) and delayed (“asynchronous”) interaction.

(1998) has identified seven ways in which this change occurs:

- From linear to hypermedia learning.
- From instruction to construction and discovery.
- From teacher-centered to learner-centered education.
- From absorbing material to learning how to navigate and how to learn.
- From schooling to lifelong learning.
- From learning as torture to learning as fun.
- From the teacher as transmitter to the teacher as facilitator.

Interactivity and Adult Learning Theory

Why is interactivity important in education? One reason is that interactivity is particularly compatible with established psychological models of learning and the central tenets of adult learning theory (Simpson & Galbo, 1986). In particular, constructivist principles help account for the importance of interactivity in distance education. Constructivism is the view that knowledge is “constructed” by the learner by testing ideas, concepts and approaches based on existing knowledge and one’s actively acquired experiences, including the views of others, and that knowledge is not merely acquired passively. Constructivist theory holds that students learn best when they actively and collaboratively participate in problem-solving and critical thinking while involved in an appropriately formulated learning activity, and that this learning involves the integration of newly acquired knowledge with pre-existing intellectual constructs.

Experts in adult learning also argue that traditional didactic teaching merely encourages passive learning, instead of the development of higher order cognitive skills needed for true education. They point out that active involvement is essential for effective learning, and adults learn best, they argue, when one can draw on previous experi-

ence, using techniques such as group discussion, simulation exercises, and problem solving. That is, going beyond mere looking and listening motivates people to learn on their own, gives students the motivation to try out new ideas, and encourages them to critically examine issues that were once simply accepted passively.

Interaction Between Student and the Instructor

Interactivity in the traditional classroom is primarily between the student and the instructor, and technology usually plays a secondary role; students can ask questions and get immediate replies. Outside the classroom students often interact among themselves by verbal means (“Did you understand how he solved problem 6?”) and may later interact by telephone, instant messaging and e-mail, three means of interactivity also available to distance education students.

Students in some distance education programs view videos of the regular on-campus classes, which include interactions between the on-campus students and the instructor (usually in the form of questions), but obviously such viewers cannot have any synchronous interaction with the instructor at the time of the lesson, although they are still able to exchange words with both the instructor (and, possibly, an academic advisor) via telephone, fax, instant messaging and e-mail.

In many cases distance education learners have no direct interaction with the course instructor, and instead deal only with an on-site coordinator or tutor. Still, provided these individuals are knowledgeable in the materials being taught and have well-developed communication skills, this should not be a problem. Such individuals are especially helpful in settings where there is a high ratio of students to instructor and/or when direct access to the instructor is not practical.

In contrast to the setting where students have no direct interaction with the course instructor, online services also exist which offer instructor-

led courses where students can log into a message board for discussions with both the instructor and fellow students.

Interaction Between Student and Content

Many educational theorists would say that interaction between the student and the content is the heart of education, whether in the classroom or in the distance education setting (or, indeed, in the setting of self-education). In order to learn effectively, the content must be presented in a way that will motivate the student and inspire thought. Most often, the material is presented as text with some graphics, and a good writing style with good organization of the material are the key elements to producing a useful document. The technology used for the document (printed paper, PDF, HTML etc.) is less important than the quality of the writing, although poor formatting makes even good writing hard to read.

One interesting notion in this context is Bloom's "alterable variables," modifiable factors that Bloom found to enhance group learning to the level of tutoring (Bloom 1984). Examples include the use of reinforcement, supplying corrective feedback, and offering cues and explanations. It would appear that use of Bloom's alterable variables would be excellent educational elements that might be introduced into the process of developing educational resources.

Interaction Between and Among Students

Students have always been able to communicate with one another in traditional classrooms, sometimes by passing notes, but usually by meeting informally before and after class. Such social interactions are important to making new friends and getting exposed to new ideas. These interactions also help in carrying out collaborative projects.

It is interesting to note that interaction between students is a somewhat new phenomenon

in distance education, having started in a big way only since the development of the Web made computer-conferencing practical. Until relatively recently, distance education students had limited interaction with other students, their interactions being primarily with the instructor, the content, and the technology. However, the advent of Web-based computer conferencing and e-mail services has changed this. As a result of this and the development of groupware systems such as Lotus Notes, distance education is moving from highly individualized instruction (as in the correspondence education approach popular decades ago) to formats that encourage students to explore topics as a group and to undertake collaborative learning. This approach is also asynchronous, which gives learners the freedom to control their learning activities in terms of time, location and choice of collaborating partners. Other technologies, such as instant messaging or two-way video conferencing, also allow for communication among students, but are primarily synchronous in nature. By contrast, computer conferencing provides for asynchronous interaction, which fits much better into the hectic lives of many adult learners. Still, the nature of student-student interaction in distance education is fundamentally different from conventional educational settings.

Some students feel that the distance education format is often weak in the area of establishing "bonding" between classmates, who are not able to get to know one another as effortlessly as in a classroom. Students usually have no idea what their classmates look like, or what their voices sound like, thereby delaying the development of any "mental image" about the people in the class until much later, once many postings have been made and students get to know one another by means of written communications. This notion is known as "social presence" (Nippard & Murphy, 2007) which may be defined as "the degree to which participants are able to project themselves affectively within [a] medium" (Garrison 1997). Social presence affects student perceived learning (Richardson & Swan, 2003), may increase student

satisfaction in online learning (Newberry, 2001), and may lead to improved emotional satisfaction (Rourke et al., 1999).

Interaction Between Student and Technology

Until recent years, educational technology was not especially capable of maintaining a high degree of interactivity with a learner, in contrast, say, to the very high level of possible interaction between a teacher and a student discussing a philosophical matter, where a series of verbal exchanges may occur that involves a cognitive effort much more advanced than mere memorization or rote repetition.

This matter will likely change favorably as computer technology inextricably advances. In particular, advances in Artificial Intelligence, educational authoring systems and scripting languages such as JavaScript will likely have a direct impact on the evolution of computer-based interactivity. Still, computer-based learning is much more complex than working through a textbook, and many students who are uncomfortable with computers see no reason to deviate from a curriculum based on a well-written textbook, particularly if accompanied by study guides and solution manuals.

Many advocates of computer-mediated distance education draw attention to the helpful aspects offered by computer-based methods, and understate the kinds of communicative and technical difficulties learners may experience. When students use complicated equipment in their learning environment, it is important to ensure the technologies used help rather than hinder the learning experience. Students using unfamiliar technologies may experience frustration, anxiety, and confusion related to computer hardware problems, software problems at the level of the operating system or the various software applications, as well as difficulties with Web access. Files may mysteriously “disappear.” Attachments sent by e-mail may be “lost”. Random “discon-

nects” may frustrate the user. Unless students are moderately familiar with computers, substantial effort may be expended on technology-related issues rather than learning the intended materials.

Thus technologies that are awkward, unintuitive or present the learner with a steep learning curve may hinder interaction and even impede learning. Various means by which technology can impede interactivity include: haphazard, unintuitive or disorganized user interfaces; poor screen layout; poor use of fonts and icons; systems that respond too slowly to user inputs; or systems that crash frequently. While a detailed discussion of this matter is beyond the scope of this review, books by design gurus Jakob Nielsen (1994) and Donald Norman (1999), are recommended as a good place to explore the nature of good and bad user-interface design.

Studies show that technical problems can occasionally render the educational undertaking to be a substantially negative experience. For instance, Hara & Kling (1999) carried out a study of a web-based distance education course at an American university, and commented that distance learners may experience problems and frustrations that are not well documented in the literature. They noted that three interrelated sources accounted for most of the problems: “lack of prompt feedback, ambiguous instructions on the web, and technical problems.” They concluded that the frustrations the students experienced “inhibited their educational opportunity”. In a related paper Hara & Kling (2000) voiced similar concerns.

Interactivity in Medical Education

The Royal College of Physicians and Surgeons of Canada (RCPSC) has long taken an active role in the post-certification education of Canadian specialists through their Maintenance of Certification (MOC) program and its forerunners. Although they use the term “Continuing Professional Development” (CPD) in referring to this process, it is, in essence, simply another term for Continuing Medical Education (CME).

The MOC program requires that members complete 400 credit hours of acceptable CPD in a five-year period to maintain specialist certification. Among the most popular means of collecting credit is through “Section 1” educational activities (attending lectures, seminars, scientific meetings, journal clubs, etc.). Other acceptable activities involve “practice audits,” “personal learning projects,” and education via medical simulation.

The RCPSC feels strongly that Section 1 activities are of increased educational value where there is an opportunity for interaction between the “expert” speaker and the participants. This is often in the form of a question and discussion period that serves to further engage the listener, as well as to clarify some of the issues that may remain unanswered at the end of the formal part of the presentation.

The MOC program requires that “at least 25 per cent of the time of a CPD event should be allocated for interactive learning.” Otherwise, the program coordinators believe, the event takes place at the expense of audience involvement, a key ingredient in learning. This view is supported by a landmark meta-analysis of the effectiveness of formal CME by Davis et al. (1999), who showed that traditional didactic methods do not generally lead to a change in clinical practice, or to an improvement in patients’ health outcomes, whereas interactive techniques are more likely to lead to a change.

Simulation in Medical Education

In many respects, simulators offer the ultimate in interactivity and appear to have an excellent future in medical education. Computer-based simulators used in medical education fall into four general categories: (1) Screen-based text simulators, (2) Screen-based graphical simulators, (3) Manikin-based simulators, and (4) Virtual reality trainers.¹

Screen-based text simulators create verbal scenarios in which the users pick one of several responses and, based on the chosen response, a new text scenario is produced. For instance, in

a scenario involving a patient presenting with a severe headache, the user may be offered options such as prescribing an analgesic such as Tylenol or getting a CT-scan of the head. Based on the user’s choice, a new narrative is then generated and more management choices are offered. Being purely text-based, screen-based text simulators are relatively simple to construct, making them popular in early medical simulation efforts. However, since they are lacking in graphical elements, they are rarely used today.

Screen-based graphical simulators such as ‘Gasman’ (Philip, 1986; Philip, 2009) and ‘Body’ (Smith & Davidson, 2009) aim to recreate elements of reality in graphic form on a computer screen, often to elucidate the processes associated with drug administration. Usually, only a mouse interface is involved. While these simulations help one understand the conceptual theory underlying clinical practice, they usually do not confer practical skills. Their strength lies in an ability to help one understand abstract concepts while remaining portable and inexpensive.

Manikin-based simulators come in various levels of complexity, but are expensive. The advanced models include a physical model of the human body and provide continuous signals representing numerous physiological parameters. While some earlier systems required the intervention of a trainer to actively ‘stage manage’ the scenario in response to interventions, others make use of computer models of human physiology and pharmacology to automatically generate appropriate responses in the manikin. In contrast to screen-based simulations, these simulators appear to recreate enough elements of reality to allow the acquisition of skills that are transferable back to the clinical environment.

Virtual reality trainers are just beginning to gain popularity, especially amongst surgical trainees. They offer a transition from the two-dimensional world of the textbook to the three dimensional world of simulated patients. The principal problem so far has been the lack of reality modeling in terms of offering a tactile ‘feel’. However,

“haptic” solutions that provide feel and heft are being actively researched in centers, often using micro-engineering techniques.

Kinds of Interactivity in Medical Education

We have already noted that, as with all areas of education and training, interactivity plays an important role in medical education. While the RCPSC emphasizes means such as question and answer sessions to achieve this goal, many other methods can be imagined. One possible taxonomy of the kind of interaction in medical education is outlined in Table 1.

Social Media in Education

Social media such as Facebook can help serve to connect millions of learners, forming a virtual learning community where information, ideas, resources and suggestions are informally exchanged, offering community members ready access to knowledge, both from experts and other students. Some social media like Yahoo Answers focus on allowing users to submit questions and answer questions asked by others. As a way to encourage participation, members may get the chance to earn “points.” Users can also comment on answers, rate questions and answers, and offer suggestions to improve the service. However, such sites have sometimes been criticized as a problematic venue for serious education because of difficulties in readily deleting incorrect answers, and a point structure that rewards participation over accuracy (Liebenluft, 2007).

Massive Open Online Courses

The Khan Academy (www.khanacademy.org) is a popular non-profit educational website created in 2006 by Salman Khan. It has delivered millions of lessons in topics as varied as physics, chemistry, biology, mathematics, astronomy, economics and

history. The Khan Academy has both enthusiasts and critics. Enthusiasts support the academy for its ingenuity, its popularity, and its eradication of economic barriers to education. Others, however, are concerned that the videos lack interaction and active engagement.

Coursera (coursera.org) is an educational technology company founded by Andrew Ng and Daphne Koller. Rather than the mini-lecture approach taken by the Khan Academy, Coursera offers hundreds of free noncredit university level courses in computer science, engineering, mathematics, business, social sciences, humanities, and other fields. In the future, students may be take Coursera courses for university credit, at costs competitive with brick-and-mortar universities, via exams administered via an online proctoring service that allows students to be watched via webcam. Similar initiatives have also been launched by Education Portal (<http://education-portal.com/>) EDX (edxonline.org), Minerva Project (minervaproject.com) and Udacity (udacity.com). All are examples of Massive Open Online Courses (MOOCs).

Course Management Systems

Course management systems (sometimes also known as learning management systems) are software platforms that provide an instructor and students with a set of resources (course document storage, e-mail, discussion threads, videos, examination capabilities, etc.) that facilitate the development and delivery of online courses. Examples include Blackboard (www.blackboard.com), Moodle (moodle.org), Pearson LearningStudio (www.pearsonlearningsolutions.com/pearson-learning-studio/), OLAT (www.olat.org), and Sakai (www.sakaiproject.org). These systems are primarily intended for asynchronous content delivery; for the delivery of synchronous content, technologies such as videoconferencing and web conferencing are often used. Examples here include the use of Skype (www.skype.com),

Webex (www.webex.com) and GoToMeeting (www.gotomeeting.com) for the delivery of lectures and for virtual class discussions.

Interactive Learning Games

Interactive games are not only intrinsically engaging, but can also serve to help develop interpersonal and collaboration skills leadership, and promote creativity, critical-thinking, and problem-solving skills (Gee, 2003). Examples range from simple “typing tutor” games, where characters are falling down the screen and the learner must stop them before they reach the ground by pressing the corresponding key on the keyboard, to elaborate flight simulation games where one can learn the principles of flying an aircraft.

FUTURE RESEARCH DIRECTIONS

Although it is taken as a given in many circles that the addition of interactivity in the learning process is beneficial, the evidence for this viewpoint is not as strong as one might expect in medical education (v. Bridges (1992)). While use of interactivity offers a number of theoretical benefits (for instance, it is compatible with the constructivist model of learning), empirical proof remains rather limited.

Despite the obvious importance of interactivity in the educational process there are a number of questions that await definitive answers:

- Does interactivity really matter?
- How, if at all, does interactivity affect learners and learning?
- Do students prefer interactive learning?
- Do students perform better when exposed to interactive learning methods?

Perhaps the best available review of this topic in a medical context is a meta-analysis by Davis et al. (1999). In their study of a small number of “well-conducted” trials on methods of CME,

they noted that traditional didactic teaching sessions “do not appear to be effective” in changing physician behavior but noted that there is “some evidence that interactive CME sessions that enhance participant activity and provide the opportunity to practice skills can effect change in professional practice.”

CONCLUSION

Adult learning theory emphasizes the importance of interactivity in the educational process. In exploring the differences between traditional teaching methods and distance education, the issue of differences in the patterns and properties of interaction in the two settings figures prominently. Students in distance education interact variously with the instructor, the content, the technology, and with other students. Although four kinds of interactivity have been identified in the literature, other models specific to particular domains are possible. Interaction with technology will likely become increasingly important in computer-based distance education, but good design principles must be adhered to for successful outcomes.

KEY TERMS AND DEFINITIONS

Adult Learning Theory: Pertaining to the art and science of adult learning. Also known as andragogy.

Asynchronous Interaction: Interaction that does not take place synchronously and so is independent of time restrictions. Examples include messages sent via e-mail, SMS or messages posted to a discussion server. Contrasted to synchronous interaction, as exemplified by classroom teaching or holding a telephone conversation.

Course Management System: Software platforms that provide an instructor and students with resources (course document storage, e-mail,

discussion threads, videos, examination capabilities, etc.) for the delivery of online instruction.

Distance Education: The delivery of instruction that does not require the learner to be present in the same physical location as the instructor.

Electronic Publication: Also referred to as e-publishing or digital publishing or online publishing, electronic publication includes the digital publication of e-books, digital magazines, and journal articles, often in HTML: or PDF format.

Interaction: Mutual or reciprocal action or influence, as with the interaction between the moon and oceans causing tides.

Interactive Learning Environment: An environment that promotes learning via interactive processes, as exemplified by computer-based training or interactive computer simulation / games.

Interactivity: Reciprocal events that involve two or more objects and actions via mutual influences.

Massive Open Online Course (MOOC): An online course (often a university course) that offers unlimited participation, open access via the web, and automatic evaluation of the learner's progress.

Social Media: Websites and applications that enable users to create and share content (e.g., photographs) or to participate in social networking. Examples include Facebook, Twitter and MySpace.

ENDNOTE

- ¹ In the world of aviation, simple simulators are usually called “trainers”, with the term “simulator” being reserved for machines that provide graphics and/or full-motion replication of aircraft motions or actions.

Medical Equipment and Economic Determinants of Its Structure and Regulation in the Slovak Republic

M**Beáta Gavurová***Technical University of Košice, Slovakia***Viliam Kováč***Technical University of Košice, Slovakia***Michal Šoltés***Technical University of Košice, Slovakia*

INTRODUCTION

Healthy population is a significant component in the process of economic growth of the country, because the full economic potential can only be achieved health. The health sector is affected by the innovation process, which includes skilled workforce healthcare sector is one of the largest in the European Union. Research and development in the health sector has the potential to reach 0.3% of gross domestic product. healthcare sector is one of the largest in the European Union, representing around 10% of the European Union gross domestic product and employs one in 10 workers with a higher than average proportion of workers with tertiary education. Support for human health is an integral part of the objectives of smart and inclusive growth and Europe 2020 (European Commission, 2011). An innovative development is necessary to exist to ensure the sustainability of the sector, as well as to achieve inclusive growth in the context of demographic change. It is not related only with the growing health needs of the population, but also pressure to increase the efficiency of the health system.

BACKGROUND

Modern medical equipment and technologies enable efficient and rapid diagnosis and treatment of diseases, hence their deployment in the health system necessity (Rosina et al., 2014). In addition to the quantifiable economic savings also it happens to humane treatment, prevention of possible complications, and thus to the elimination of the additional costs in the event of subsequent medical care for patients. Timely and successful diagnostics will save unnecessary medical procedures according to experts who make up one third – analysis of the European Association of medical technology Eucomed. Modern medical technologies, modern approaches to diagnosis and treatment combined with early detection also allow to shorten hospitalisation time for some diseases from several weeks to a few days. Reducing the number of hospital admissions and inpatient treatment time and replace feature to make it by the day surgery has been a global trend lately (Gavurová & Šoltés, 2014). In addition to radical savings in the health system derived from therapeutic and diagnostic procedure in conjunc-

tion with application of the latest research findings and health technologies, the macroeconomic view on this issue is also important. Within the medical technology industry in Europe more than 500,000 people are employed, making it a production of medical technologies important element of the gross domestic product of individual European countries. Upgrading of medical technologies occurs not only to improve them, but also to their constant replacement of modern and innovative technologies in the short term. This is confirmed by the fact that, for instance in 2012 the European Patent Office received more than 10,000 patent applications in the field of medical technology and the number is increasing. It is related to the significant progress in research and development.

Despite the positive development of modern medical technology an important component in the process of successful diagnosis and treatment becomes their availability. Availability of advanced medical technologies in the Slovak Republic is not proportional and regionally balanced. There are various problems that have long-term systemic nature (Gavurová & Šoltés, 2014; Kneppo et al., 2014).

If we look at the situation abroad, the density of medical equipment in different countries varies considerably in the European countries – for instance in the case of devices for x-ray computed tomography and magnetic resonance imaging. The Greeks have ten times more magnetic resonance imaging devices for a person like the Hungarians, the Austrians three times more than the British. The Greeks have the most devices for x-ray computed tomography, there are three times more x-ray computed tomographs per person than the Dutch have or just like the Italians. The differences are evident not only among countries but also within countries. For instance, there are four-fold differences between trusts in the number of top medical equipment in the United Kingdom. If we conducted an international comparison of the other kinds of medical equipment in the country, we would have confirmed the existing significant differ-

ences between countries. Therefore, it is difficult to determine the optimal number in the country.

The primary objective of introducing and using of the variety of health technology is to improve the health of the population of the country. The Slovak Republic has still lacked standard procedures to govern the rational use of various diagnostic technologies. The negative consequences include unnecessary tests, which are also reflected in the economics of the Slovak healthcare system (Gavurová et al., 2014). There is no methodology to determine the optimal number of medical devices. Their introduction into medical practice is now accompanied with many obstacles. These are linked with the strategies of health insurance companies and with the waiting time for examinations -- waiting lists for procedures. Waiting, keeping the patient on the waiting list respectively, waiting time refer to the time between the placing of a patient on the waiting list and its disposal (Roberts et al., 2004). In relation to the effective healthcare, this is generally the time between approval and implementation of procedures (Mužik & Szalayová, 2013). According to the Organisation for Economic Co-operation and Development one of the reasons for the increase waiting lists has been a significant advance in surgical techniques and anaesthesia during the last two or three decades, what greatly have improved range, safety and efficacy of surgical procedures (Siciliani & Hurst, 2013). Many of the procedures have carried out at lower unit costs consequently a dramatic increase has occurred in demand for surgery, especially in effective – not acute – procedures, such as cataract surgery, hip surgery, or bypass in all the Organisation for Economic Co-operation and Development member countries. Waiting lists are a serious problem in these countries, including the Slovak Republic (Eriksson & Björnberg, 2009, Mužik & Szalayová, 2013). Long waiting times for efficient performances are typical for countries that combine health insurance with no or low deductibles and limited capacity of the patient (Siciliani, 2003). Fewer occurrences are

in countries with insurance schemes, in which choice of health insurance is allowed.

Waiting times for examinations cannot be reduced by introducing a greater number of devices in the diagnostic process, because, for example, many machines on magnetic resonance imaging or x-ray computed tomography examinations are currently used only a few hours per week (Mužík & Szalayová, 2013). A significant limiting factor for higher and more efficient use is mainly contractual limits by health insurance companies that this whole mechanism availability and use of appliances targeted manner.

ANALYSIS

Our analysis is based on the individual types of the medical equipment used in the healthcare facilities. We have applied categorisation of this equipment according to National Health Information Center (Národné centrum zdravotníckych informácií) of the Slovak Republic that differentiates twenty-nine types of the healthcare devices. We have focused not only on this categorisation, but also on the localisation of this medical equipment from a view of elementary administrative division in terms of the highest level of self-government in the Slovak Republic. There are eight self-governing regions, where the Banská Bystrica Self-governing Region, the Bratislava Self-governing Region, the Košice Self-governing Region, the Nitra Self-governing Region, the Prešov Self-governing Region, the Trenčín Self-governing Region, the Trnava Self-governing Region and the Žilina Self-governing Region belong.

Dataset

Our dataset contains data coming from seven years from 2008 to 2014. For each year every type of the medical equipment in counted according to its localisation in the particular self-governing regions.

At first, the basic look at the distribution of the individual equipment types is offered with total numbers of these types and in the separate self-governing regions.

Figure 1 displays localisation of the equipment types in the separate self-governing regions. The x axis shows order of all the equipment types recognised by the dataset from the National Centre of Health Information of the Slovak Republic and the y axis signifies the administrative division of the Slovak Republic at the level of the territory units in terms of the self-governing regions. Grey shading of the x axis tags represents a share of the number of equipment of that type in the total number of all the 29 equipment types on the x axis, respectively a share of the equipment localised in the individual self-governing regions in the total number of the equipment in the whole Slovak Republic on the y axis. Circles' diameter in the individual cells and its shading are determined by a share of the particular equipment in the total number of all the equipment in the peculiar self-governing region in a column way and also by a share of the particular equipment in the total number of all the devices of that type in the whole Slovak Republic in a row way. Empty cells express zero number of that type equipment (Bendixen, 2003).

At the beginning of the observed period in 2008 the most numerous type of medical equipment is monitoring device with 2423 pieces in the whole Slovak Republic. The Bratislava Self-governing Region has exactly 500 items, what expresses also the highest number of any type. On the opposite side there is positron tomograph, which is the least numerous type of the medical equipment. There are only 3 such devices in all the regions.

There are 8800 devices together in all the healthcare facilities. From 29 types, 9 of them are not localised in everyone region – the mostly absenting is positron tomograph in 5 regions and then brachytherapy apparatus in 3 regions.

At the end of the observed period in 2014 monitoring device remains the most numerous type. Its number was increased by 57 pieces to

the total number of 2480. The highest share belongs to the Žilina Self-Governing Region with 519 devices. The least numerous type a positron tomograph was doubled by a brachytherapy apparatus, which are represented by 7 items in all the regions together.

There are 9192 medical devices in all the Slovak healthcare facilities. There is to note that also these two equipment types – positron tomograph and brachytherapy apparatus – were missing in the largest number of the regions – in 4, while on the one hand positron tomograph was added

in 2 regions and on the other hand brachytherapy apparatus was set aside in 1 region.

Localisation of the Medical Equipment Types

To analyse distribution of the devices throughout the Slovak Republic, we quantify an equipment profile for each type of the equipment in 2014.

This profile performs as a share of that type equipment localised in the particular self-governing region of the total number of the equipment in the whole country.

Unsuitable localisation of the devices among the self-governing regions in 2014 is seen mainly in a case of the least numerous types that are mentioned above.

Table 1. Equipment profiles in 2014

Legend: The same as for Figure 1.

To examine profile of the self-governing regions from an equipment type point of view regional equipment profile is applied. It characterises the particular type of medical device in the light of all the self-governing regions. Regional equipment profile expresses a mean share of all the equipment profiles in each region.

Regional equipment profiles demonstrate average localisation of the equipment types according to the self-governing regions. The largest decrease all over the observed years appeared in a case of the Bratislava Self-governing Region, where regional equipment profile sank from 0.2458 in 2008 to 0.1871 in 2014. In terms of the absolute numbers of equipment it means fall from 2163 to 1720 devices. The largest year-over-year change happened to the Košice Self-governing Region, where in the last observed year was reduction from 0.1963 in 2013 to 0.1292, which in the absolute numbers mean loss of 881 devices – a 42.58% share of 2013. The Banská Bystrica Self-governing Region keeps its share on the same level roughly. All the other regions were slightly increasing their regional equipment profiles throughout the explored period with the highest year-over-year increment between 2013 and 2014.

Equipment Distribution

Distribution of the medical devices among the healthcare facilities have to take into account several parameters. From our point of view, we

look at the localisation at level of the highest tier self-government. Equipment spreading depends on financial capacity of individual healthcare facilities in the region, as there are public and private ones. Methods of their financing are considerably differentiated. Public healthcare facilities, whose debt steadily annually increases, have limited investment opportunities unlike other private healthcare facilities, which operate at a profit. It is difficult to pick up a need for proportional distribution. To get more detail analysis it is necessary to obtain information about investment strategies and financial possibilities of healthcare facilities and contracted volumes of medical services by health insurance companies.

There is to note that statement about oversizing or undersizing of numbers is based only on conclusion of our correspondence analysis.

Diagram marked as Figure 3 demonstrates localisation of the equipment types according to the individual self-governing regions regarding its share in these regions and its share among all the devices of that type too. Quadrilateral area of one cell represents a share of a number of the particular type equipment in the total number of all the equipment in the whole Slovak Republic or in the particular self-governing region. Blue shading expresses a situation, when a number of the particular type equipment is higher than it was in a case of their uniform distribution among all the healthcare facilities in the Slovak Republic. On the other hand, the red shading indicates a

Table 2. Regional equipment profiles

Legend: The same as for Figure 1.

state where there is a smaller number of that type equipment localised in the specific self-governing regions than it was in a case of uniform localisation.

The most unsuitably distributed device among the self-governing regions at the beginning of the observed period in 2008 is dialysis monitor. There were 457 monitors in the Bratislava Self-governing Region, where it reaches a dataset's maximum value of Pearson residual. It creates a share of 66.42% of this type total number and this can be considered oversized. Such a situation is reflected in the lowest Pearson residual in the five other self-governing regions – in the Košice Self-governing Region, the Nitra Self-governing Region, the Prešov Self-governing Region, the Trenčín Self-governing Region and in the Žilina Self-governing Region – where a number of dialysis monitors is undersized. There are still two extreme cases – electroencephalograph and high-frequency device. A number of electroencepha-

lographs in the Trenčín Self-governing Region is 129; although it is not a minimum value of all the regions, regarding the other equipment, it can be marked as undersized here. The second one extreme case is created by high-frequency device in the Košice Self-governing Region, where 79 devices are situated, what is a share of 27.92% of all that type devices in the Slovak Republic. Speciality of this case is the fact that no other region suffers from an undersized number of that type equipment. Such an instance only confirms that these analysis takes into account not only distribution of the equipment type among the regions, but also localisation of other equipment in the same region.

The situation in localisation of the equipment changed considerably over the explored period. In a case of dialysis monitor it turned the opposite way – its number decreased in the Bratislava Self-governing Region to 100, what represents a

Figure 4. Equipment localisation in 2014

Legend: The same as for Figure 1.

share of 12.25% of this device total number in the whole country, whilst in the Košice Self-governing Region its number increased to 151 with an 18.5% share in the Slovak Republic and this region is deliberated to be oversized by this device. Looking at the previous figure, there is another unsuitably localised medical device – monitoring device, whose situation does not change very significantly compared to the beginning of the observed period in 2008. Existing relations were only deepened more. Partially new situation occurred in cases of electromyograph and ultrasound device. Lack of the electromyographs in the Bratislava Self-governing Region in 2008 moved to Prešov Self-governing Region in 2014. In a case of ultrasound device, its lack in the Košice Self-governing Region in 2008 disappeared and raised in the Žilina Self-governing Region in 2014. On the other hand, its surplus from the Nitra Self-governing Region in 2008 moved to the Bratislava Self-governing Region in 2014.

Similarities in Equipment Localisation

State of medical equipment localisation among the healthcare facilities is very various in the Slovak Republic. To measure differences between situations in two equipment types we compute chi-squared distance.

The largest difference among the equipment types was in 2008 between brachytherapy apparatus and positron tomograph at level of 4.305. The largest similarity connects monitoring device with endoscope, laparoscope and arthroscope – their mutual distance is only 0.026. In 2014, the largest difference was between the same types as at the beginning of the observed period, but sank to 3.427. On the opposite side the two most similar devices stand – laser and ultrasound device that are separated from each other by only 0.008. In 2008, they lie at distance of 0.43. In the previous year, the most similar devices were in 2014 more distant from each other by 0.105.

Legend for the axes of Table 3 is the same as for the y axis of Figure 1. Legend for values of Table 3: Numbers written in the upper right half of the matrix belong to year 2008 and numbers displayed in the lower left half of the matrix belong to year 2014; main diagonal is the same for the both years because of its characteristic.

If we compare individual distances between the equipment types at the beginning and at the end of the observed period, we could find changes of similarities of the same equipment type pairs. There are two cases, when no change happened after the explored period – between angiograph and group of colonoscope, sigmoidoscope and proctoscope and then between laryngoscope and mammograph.

FUTURE RESEARCH DIRECTIONS

The main results of the executed analysis can be summarised subsequently. The most numerous healthcare equipment is monitoring device, dialysis monitor, electrocardiograph, and ultrasound device. The total number of the healthcare equipment was slightly increasing from 2008 to 2013, but in the last observed year 2014 fell down by 16.44% to 9192 devices. Some of the equipment types are not localised in each self-governing region, although during the explored period a few types were supplemented in the regions where there was lack of them.

Shares of a number of the equipment were throughout the observed period various. The Banská Bystrica Self-governing Region retained approximately the same shares, whilst share of the Bratislava Self-governing Region was sinking throughout the whole period from 24.58% down to 18.71%. In the Košice Self-governing Region, a share was raising from the beginning of the period to 2013, but then in the last year fell sharply from 19.92% to 18.71%. In the other self-governing regions, shares remained the same, but there was their small increase in the last observed year 2014.

Situation in the medical equipment types localisation was as in the successive lines. Dialysis monitor was oversized in the Bratislava Self-governing Region in 2008, but in 2014 already undersized. Oversizing of this equipment occurred also in the Košice Self-governing Region oversized in 2014. Another apparatus oversized in this region was high-frequency device in 2008. Unsuitable

localisation in 2008 with deepening of this state throughout the observed period occurred with monitoring device. Electromyograph appeared undersized in the Bratislava Self-governing Region in 2008 and in the Prešov Self-governing Region in 2014. Ultrasound device is a type of medical equipment with uneven distribution across the country too. Its number was undersized in the Košice Self-governing Region and in the Nitra Self-governing Region oversized in 2008, in the Žilina Self-governing Region undersized and in the Bratislava Self-governing Region oversized in 2014. All these numbers suggest there is missing systematic distribution of the medical equipment (Pharr, 2013; Otawová et al., 2015). This issue should be subject to discuss in future (Zavadiľ et al., 2016).

CONCLUSION

The development process and the mortality of global aging are processes that have impact on the system in the country and are limited by a number of determinants. In addition to health insurance system, expenses intended for healthcare, a network of healthcare providers and demand for them an important role is played in the quality of treatment processes and sophistication of medical technology. This is varied all over the different countries its level is influenced by the historical development of scientific and technical progress and the rate of implementation of research and development into practice. There is no long-term monitoring of the status of medical equipment in healthcare facilities in the Slovak Republic. Some of the healthcare facilities have still limited access to tomography or magnetic resonance imaging device. A critical condition occurs when in urgent cases – often in hospitals – patient wait for x-ray computed tomograph for several weeks. It is questionable whether the condition is caused by a lack or absence of financial resources from health insurance companies. At the present time, the Slovak economy health system is set so that

it does not allow natural reproduction of health technologies. Healthcare providers are not able to secure the financial resources to purchase new equipment during its operation life. It is therefore necessary to address this urgent problem and to deal with the availability and quality of instrumentation and to communicate at government level, the need to purchase diagnostic equipment for coordinating public health department, an issue to initiate setting of adequate normative that would force healthcare provider to modulate equipment in corresponding time period. An alternative to solve this problem would be the introduction of the process of financing healthcare technology from the state budget or by reimbursement from health insurance companies. Investments into radiological technology should be one of the most important indicators monitored within the Slovak health service strategic framework. Another issue is unsuitable distribution of medical equipment all over the Slovak regions, where are significant regional disparities between healthcare providers. They are not only in the field of localisation of the particular types of the medical equipment, but also in a way related to a share of the equipment in the individual self-governing regions of the Slovak Republic. These outputs should serve as a monitoring platform in evaluating accessibility and quality of healthcare technologies for use in this country. To obtain more detailed conclusions from the analysis we would need to have access to more data, which is the subject of our current research activities and cooperation with the institutions of the healthcare system.

KEY TERMS AND DEFINITIONS

Efficiency: Known as effectiveness or productivity generally refers to the efficiency of the used resources and the utility obtained by their use. It is a ratio of inputs and outputs of an activity or a system.

Equipment: A device used in healthcare facilities to perform health care.

Health Care: A range of activities and measures leading to prolonged and sustained life of individuals, to improve quality of life and its protection, promotion, strengthening, improving and restoring health.

Health Policy: A guideline applied to health care system by state authorities responsible for health services.

Healthcare Facility: A place where medical equipment is used to perform health care.

Healthcare: A social set of professional knowledge institutions, establishments and authorities, workers and their corresponding activities, serving specifically to providing health care with an appropriate order to promote, preserve and restore health.

System of Health Care: Provision of health services. It is one component of health care and health policy determined by the state.

Use of Technology in Problem-Based Learning in Health Science

INTRODUCTION

In current tertiary education environments, Information and Communication Technologies (ICT) has impacted on both the design and delivery of education to students with a strong focus on e-Learning (Clothey et al., October 2012). Interactive technology incorporating e-Learning has the ability to promote active learning, seeking information through accessing multiple modes of information and self-directed individually paced learning (Dede & Fontana 1995; Kahn 1993). Tertiary education faces a number of common challenges such as increasing class size, diverse cultural backgrounds, limited resources and teaching space facilities as well as concerns around the alignment of course curriculum for graduate capabilities (Gunn & Harper, 2007)(Smyth, Andrews, Caladine, & Bordujenko, 2011). To meet these demands, institutions such as Griffith University have had to employ existing technologies to increase learner autonomy. Through the introduction of e-learning activities, students have more flexible access to education and training, whilst avoiding increasing costs to campus infrastructure, laboratory staff and resources. This article will discuss the current use of technology to deliver various innovative forms of e-learning and blended problem based learning (PBL) as well

as some models that are being developed and trialled at Griffith University to train undergraduate Medical Laboratory Science (MLS) graduates for the global health workforce. Some of these technological models were designed and developed by the authors from Griffith University. These include digital slide microscopy, introduction of computerized cell differentiation counters, 3D virtual reality (a 360 degree panoramic view of a live pathology laboratory), demonstration videos and the use of electronic portfolios (e-portfolios). Throughout the 4 years of the degree program, simulated and real world case studies have been developed and scaffolded across the courses within the program both vertically across the year levels and horizontally across courses within same year level. This strategy of mix mode use of technology aligns with the cognitive learning principles identified by Swann (2013) suggesting that inclusion of multimedia requires learners to split their attention between different means of instructions and helps mentally integrate the learning.

Although digital microscopy has been widely used in laboratory based teaching for some time, its advantages have been limited due to its restricted access of images for students. With the recent development of Image Scope, this software platform has allowed students to view Aperio scanned slide images on multiple computers across campus and

off campus and has enabled students to access their dedicated course pathological slides without having to enter into a physical containment 2 (PC2) laboratory facility. Standardisation of training materials and extending the life capacity of rare and exotic case based slide sets that can degrade over time (such as loss of staining intensity due to long term storage) have also been achieved through the use of digital microscopy.

Simulation computer based morphology programs using Raspberry Pi mini computers have also enabled institutional laboratory facilities to incorporate electronic cell counters into haematology based practical sessions. This allows students to familiarise themselves with current cell counter technology found across private and public pathology laboratories. The computer system has been able to enhance educational learning and permits software development to be tailored to intuitional needs, without the burden of having to outlay large financial costs.

Furthermore, use of short demonstration videos showing different laboratory techniques have shown to improve student experience in understanding the techniques in detail. The demonstration videos had a significant impact through saving time and reducing the teaching load during laboratory sessions. Additionally encouraging students to develop their e-portfolio, a collection of their learning, accomplishments and experiences can greatly increase their employability. The use of e-portfolio has been recommended by a number of universities as it helps the student to develop their cognitive skills from self-directed learning. As the emergence of new technologies transform our traditional classrooms into virtual educational facilities, key challenges faced during the process, and issues yet to be addressed will also be highlighted in this article. As the demands for education and training continue to increase to meet the demands of current and future workforce, this article will focus heavily on how e-learning tools and blended PBL have impacted on MLS students studying at Griffith University and the challenges that were faced from both students and teachers.

BACKGROUND

Current electronic learning (e-learning) tools along with recent advances in Information and Communication Technologies (ICT) have significantly increased students access to evidence and problem based learning techniques (Clothey et al., October 2012). This has impacted on both designing and delivering education to health science students with a strong focus on e-learning (Gértrudix Barrio, Carmen Gálvez de la Cuesta, Álvarez García, & Valle, 2007; Kirkwood & Price, 2005; Salmon, 2011). Traditional teaching in classrooms accounted for conventional academic based didactic teaching, where investigator initiated and discipline based knowledge is taught in isolation. Today the face of learning and teaching is changing to context driven, problem based, work integrated, transdisciplinary and interprofessional knowledge, where the primary focus is on building an effective and efficient team to work for a short period of time on solving a specific problem from the real world (Gibbons, 1994)

E-learning technology can act as an active instigator for creating constructivist teaching methods and active learning strategies to enhance student knowledge and prepare them for the digital age. This mode of teaching can also enable the students to develop skills such as critical analysis and personal interpretation of knowledge (Cummings, Mason, Shelton, & Baur, 2015). E-learning has been a dynamic part of the educational landscape since the start of the 21st century and has been defined in various ways over time (Sangrà, Vlachopoulos, & Cabrera, 2012). Massy and Zemsky (2004) suggest three major categories of e-learning. The first category of e-learning described as distance education where courses are delivered almost entirely online via the internet. The second and third category of e-learning termed electronically mediated learning is where learning materials are digitally delivered through various technologies and e-learning is facilitated by transactions software. The software management systems organise and manage teach-

ing and learning schedules. In relevant terms for the purpose of this article, Ashwin (2006) also defines it as 'any form of the new technologies or applications in the service of learning or learner support' which includes any software, hardware, digital resources or technology to deliver and support education e-learning. It can also be replaced with mix mode learning where technology is used to replace some of the face to face teaching with technology mediated teaching. Even though there are many definitions for e-learning, it is evident that all e-learning forms may provide a learning opportunity for individuals to use various e-learning simulation and real case base learning tools, to produced more positive learning gains than traditional lecture methods (Cummings et al., 2015, Lencastre & Coutinho, 2015).

Griffith University Bachelor of Medical Laboratory Science program uses a combination of all the above means of e-learning to deliver a four year program preparing graduates for the global market. The early adoption of an integrated, automated, central and supported e-Learning environment allows reliable and ubiquitous delivery of services, in combination with other in-class learning tools. With increasing use of smart devices by students, learning-space technology is being delivered as software to the student's computer instead of hardware to the learning spaces. This enables Griffith University to encourage students to actively learn not only in the classroom but also at home or while travelling, and permits the use of new technologies in an economical way. Similarly health institutions using simulated 3D virtual videos can encourage and motivate not only students to practise critical thinking and reflective skills but to also allow new training methods for all staff types to revise and train on analysers that are not regularly available for training. Simulations can replace laboratory activities that can reduce the costs of lab resources such as time, equipment, supplies, staff expertise, and minimise health risks associated with dangerous activities (Cummings et al., 2015). In an edited book series by Clothey et al. (October 2012), a

study by Robyn Smyth, Trish Andrews, Richard Caladine, and Jason Bordujenko discuss the great potential for use rich media technology across a number of Australian universities in reducing costs and environmental footprints. They also found similar findings compiled from the National Centre of Science, Information and Communication Technology and Mathematics Education for Rural and Regional Australia (SiMERR) that the greatest benefits of using rich media technologies helped improved collaboraiton, convenient, reduced the ease of travelling, cost effective and promoted deeper discussions of course material (Clothey et al., October 2012).

E-learning can also promote inquiry based learning via exploration and can be individualised to match learners need and training requirements (Cummings et al., 2015). In a case study by Charl Wolhuter, Hennie J. Steyn, Elsa Mentz, and Ferdinand J. Potgieter in (Chapter 4) of Clothey et al. (October 2012), they found that the launch of blended leaning classes across South Afriacn universities, were found to be more positive than traditional face to face teaching structure as it allowed for flexible language choice, helped with the demands of increased enrolments and strained teaching resources.

MAIN FOCUS OF THE ARTICLE

The authors at Griffith University developed innovative, technology-based resources, to give students 24 hour access not only to PBL cases, lectures and published material but also digital technique videos and electronic haematology (e-Haem) Atlas which was developed by imaging our actual blood films of various disorders collected from Victoria, New South Wales and Queensland. Whole slide imaging (WSI) is a conventional way of digitally scanning slides in order to produce a virtual image (Pantanowitz, Farahani, & Parwani, 2015). WSI technology has been employed worldwide in pathology departments and has overcome barriers such as limited glass slide cases, faded

stained films stored over a number of years, use of slide sets at home or outside of a laboratory facility and allowed the standardisation of training sets for all students. With flexible slide accessibility, this complements student's morphology skills gained by actual microscopy in the laboratory, without the need for a demonstrator during students' voluntary self-study period. Suggestions were incorporated from peers to use videos of actual blood flow, platelet and WBC activity to help students understand the concepts easily. These teaching strategies build students' self-confidence, employability, and capacity to apply their skills and knowledge to a range of contexts not just within the Australian workforce but also relevant to the global workforce. These new innovative tools take the "classroom to the students" to enhance flexible learning where the software is available on every computer for students on campus as well as on their personal electronic devices.

For vertical and horizontal scaffolding of students learning across various courses an e-Portfolio is being rolled out to monitor and support student progress on and off campus; in collaboration with: Haematology Technical Staff, Curriculum, Assessment & Technology, Technical Solutions (Electronics), Network and Collaboration Services, Information Services, Corporate Technology Infrastructure and Griffith IT security teams. These innovative ways of using technology as a mainstream teaching tool has been recognized by peers from other institutions and countries resulting in multiple presentations about this curriculum design and teaching strategies within Australia and overseas, including as invited guest speaker.

Some of the techniques filmed at Griffith University were reviewed and discussed as part of the pre-laboratory session prior to each laboratory class. At this stage students were assessed by providing verbal answers and sometimes written responses on the worksheets provided for the case study covered in that particular practical class. Some of the questions asked were related

to the techniques they had viewed before physical demonstration of the techniques in the class. The assessment for Histology and Haematology courses includes mid-semester and end of semester practical exams. The impact of the videos on the routine laboratory and practical exam assessment were determined via a paper based survey and a formal question is included in the student evaluation of the courses.

A few of the methods filmed for MLS program were re-taken and edited after initial use, based on the industry and student feedback. Therefore some techniques videos which were implemented as part of teaching tool were complemented by incorporating still images of the same techniques provided to students. Responses to the modified teaching videos were very positive. Similar responses were also received from the teaching team, including demonstrators (experienced senior industry practicing scientists), as this allowed them time to focus efforts in improving students skills. Since the video of the whole set of the techniques was not available to any class at the start of the semester, official student evaluations could not be performed.

In 2014 all the videos formed a component of teaching material on the university's course website. It was ensured that each technique was made available for respective courses online at the start of semester and students were surveyed at the end of semester to obtain feedback on their experiences.

A current project underway in collaboration with staff of various departments at Griffith University is to develop and implement a Raspberry Pi2 (RPi) linked to old LCD monitors with built-in USB port to use as keyboard for the input. The RPi 2 systems are an inexpensive credit card sized computer that can be personalised to run an Ubuntu Linux operating system whereby programs such as the cell differential counter can be programmed and set up for individual use. RPi was founded by the not-for profit Raspberry Pi foundation in the United Kingdom for use in education to

allow children to familiarise themselves with computer hardware, programming and to enhance their computing learning experience (Ioannou, Ioannidis, Papadopoulos, & Tapeinos 2014). At Griffith University, instead of using this as a teaching tool only, we have incorporated the use of the RPi to program and run an electronic cell counter without having to outlay large costs for electronic cell counters available on the market. It also develops the skills of students who can familiarise themselves with the process of performing differentials using the computer based technology that is commonly found in industry pathology laboratories. By personalising the cell counter program we can allow students to perform white cell differential counts in class electronically and save these case base differentials on a file format which can be collated as part of e-portfolio for future review alongside digital images that can be accessed outside of the laboratory or of campus.

Primarily RPis will be used as an electronic cell counter device; however it has the potential to be used as minicomputer for the laboratory where it can allow the automatic connection of cameras to the microscopes networked in the teaching laboratories. This application of RPis will allow students to build their e-portfolio across all year levels as an evidence of competency of the skills gained during practical laboratory sessions in the classroom as well as in industry on clinical placement with endorsement by respective academic and industry supervisors. Upon graduation the students can then carry the same portfolio to job interviews.

E-portfolios are controlled by students for sharing certain folders with the academic and industry supervisors. This allows staff to monitor in real time the progress of the students and provide them with in time feedback and guidance instead of waiting until the end of semester and giving them final grades only. Also these portfolios can be carried by students across all 4 years of their study and they can use them to compile all their ongoing class work in other courses (they

develop folders/portfolios for example blood and tissue slides to identify the diagnostic features of the tissues and blood cells) in Haematology, Histology & Histopathology to gain multi skilled experience. Instead of carrying multiple folders with them to the clinical placement they can have all the material in one e-portfolio for future reference as well as an evidence of their competencies endorsed by academics and industry supervisors when they apply for jobs in workforce.

RPi in particular can be extremely beneficial for microscopy training in Haematology, Histology and Histopathology courses, with application in Clinical Biochemistry and Clinical Microbiology during first 3 years of the program and e-portfolio from 1st year through to 4th year. Assessment is an important driver for educational practice (Guskey 2003). E-portfolio can be used as an effective platform for formative assessments. With e-portfolio, students will have access that they control but can share files/folders with their academic supervisors as well as industry supervisors when on clinical placement. This will allow students to have all their study material across the courses in one single portfolio and will allow the supervisors to monitor their progress in real time to provide timely comments and feedback particularly in 1st year and 4th year where they have to keep a weekly reflective journal as part of their main assessment instead of end of semester final exam. Any work done by students on or off campus as part of an assessable critical reflection can be saved on their e-portfolio directly or through their external storage device. It will be very beneficial to have a user friendly system where students can save their reports and tissue/blood slides features to take with them to clinical placement and job interviews upon graduation, with their supervisors comments/feedback and endorsement of having met competencies.

Digital, role play, and simulations have become increasingly popular in higher education to provide a more authentic and engaging learning experience for students. There is extensive evidence

that ICT increases motivation, confidence and engagement (Blamire 2009). The virtual Reality 3D pathology experience project is underway. The purpose of this project is to show in the classroom and teaching laboratory the routine functioning, daily maintenance required and other basic details of the equipment routinely used by most laboratories worldwide but not practical or realistic for the universities to have these pieces of equipment in their schools or departments. This will allow students to have a better concept of automation in addition to all manual methods they perform at the university. With close attention to design, development and implementation of how to use and maintain various laboratory analysers' universities can increase the professional capabilities of students as well as new and experienced staff from rural and multi-skilled emergency laboratory health scientists that require this skill in the workplace.

By sharing the interactive 3D images of various instruments and explaining the principle behind each test, students can get a better understanding of daily maintenance and simple troubleshooting. Furthermore, by actually filming the instrument in action, as shown to new staff while training upon initial employment, it could help both the students and trainee scientists to gain a better understanding of the processes and acquire an overall representation of procedures prior to hands on experience.

Industry senior administrators, management and scientists-in-charge are excited about the idea and can see enormous benefit both for students work readiness and their new employees' standardized training. Utilisation of the facilities at the Gold Coast University Hospital was suggested as our students visit these labs in 1st year of the program and senior scientists can explain the whole process in each of the departments. Incorporating this virtual laboratory interactive sessions across various courses in 3rd year courses prior to clinical placement, students will be better prepared for placement and industry should find these graduates to be more work ready than other university graduate clinical scientists.

Issues, Controversies, Problems

There have been several issues that the teaching team came across during the development and incorporation of the e-learning technologies. Time was one of the major issues that the teaching and technical team had to face. Collaboration on projects can also be time consuming as different parties need to identify the project's objectives before identifying roles that are critical to driving the process. Development of the 3D virtual reality video was a collaborative project that required active participation from various departments such as the pathology team from the hospital, the teaching team from the University and the filming crews. Issues such as time constraints and communication between departments have been some of the major causes for the delay of the project. Furthermore the 3D virtual reality video is the representation of one of the most modern and fully automated laboratories however the equipment shown in the video cannot be universal as different laboratories depending on their geographical location, workload, patient population needs and financial capabilities may have different analysers performing the same tests. Similarly, the development of RPi's as cell counters has taken a lot of time to trial and program the software to ensure it is robust yet functional enough for student and staff use. Understanding how software programs work and what is required had to be communicated frequently between the software developer and haematology staff to perform certain functions and make the program user friendly.

The paradigm shift from face-to-face learning using mix mode learning is heavily based on technology and its consistency in delivery and accessibility are still institutional barriers that can decelerate learning potential. Accessibility of Aperio e-Atlas images can be improved by Image Scope, however data capacity and storage facilities of each slide image are yet to be resolved. Current limitations of WIS such as a lack of higher power magnification, image quality, digital slide storage and downloading massive file sizes over slow networks have proven to be an issue for

both students and staff. Institutions need to work alongside Information network Services (INS) to overcome online data storage and for students to be able to access and deliver data without having to use their own storage/ hard drive devices.

The main complications with the e-portfolio have been sharing their reflective journals with their respective academic and industry supervisors. Issues such as software incompatibility between various operating systems has inhibited the supervisors ability to monitor the student's progress in real-time. There has also been another issue, where by the assessment policy of university requires the same format of portfolio between students, however software incompatibility between operating systems does not allow that all the time.

Facility spacing and networking still remains an issue even with the adoption of RPi computers. RPi requires power outlets and networking ports in order to optimise cell counters and have the added features of printing and sending across real time e-portfolio entries. Laboratory facilities that do not support ethernet ports at every student station can propose a costly issue for institutions that would like to network their RPi. Alternatively by installing each RPi device using old monitors and PC2 compliant mouse and keyboards, can take up a reasonable amount of bench space that is predominantly taken up by other lab equipment such as water baths, microscopes and centrifuges.

Technology advances very quickly and to maintain or keep up to date with these changes requires constant updates and key accountabilities to continually support and upgrade systems, links and connections and can be a financial burden. With a range of advancements in e-learning technologies, studies have also shown that there is an increasing divide between the levels of access to the technological resources but also between the abilities of the user to benefit from these learning tools. And with an ever increasing access to IT, there has been a significant shift that has not only caused a digital divide but also a cognitive divide between students based on their level of literacy within the IT medium. One of the many

reasons for this divide can be the diversity in the rate by which technology is being incorporated into the early education system across different universities and countries (Cox, 2013).

SOLUTIONS AND RECOMMENDATIONS

Several strategies were devised to overcome the issues that were faced by the teaching team. Funding schemes can help start-up costs and take the load off elements and their financial burden. Sharing costs between a numbers of groups can also help reduce budget concerns and increase collaborative use of technology enhancing tools in delivering a number of courses. Action working parties have also been developed to help collaborative efforts to maintain good communication and keep everyone updated of their roles and responsibilities

For collaborative timetabling of the 3D virtual filming process, the filming crew was requested to start filming before the morning round of patient sample collection from the different wards because most of the start-up and maintenance on different equipment is performed early in the morning prior to early morning blood and sample collection in the industry. The student will be informed by annotation about the variation in equipment and changing technology that may lead to them working with different pieces of equipment. This will be reinforced by starting the presentation with an explanation of the same.

The students who are unable to share their reflective journals from the e-portfolio, due to different operating system or software variations with their respective supervisors will be requested to upload their assessment using Microsoft word as an attachment to e-portfolio. This is not an ideal solution but provides at least some support through occasional even though not regular feedback to students.

To combat limited laboratory space issues, the upgraded version of raspberry version Pi 3 which has a Wifi and Bluetooth capability as well as the

new Rpi touch screen monitors can provide us with a portable solution to ethernet cabling and reduce lab space usage. The implementation of a customized keyboard with copper or silver loaded plastic and antibacterial keys we can reduce the size and still be able to comply with laboratory health and safety standards.

As developments in technology continue to advance, processing powers of computers, cloud storage solutions and increases in data transfer speed will help ease the burden of slow data image transfers and increase the accessibility of slide images with better quality images. Similarly upgrading Aperio scanning imager to increase the number of slide sets being scanned can also reduce the predicament of time restricted technical staff.

Finally feedback from students and educators can help identify specific e-learning tools that are beneficial and how they can best be managed or improved.

FUTURE RESEARCH DIRECTIONS

Although there has been a significant raise in the usage of e-learning technology in various programs, the need to design and provide a more engaging and high quality content is crucial for creating an effective learning atmosphere for learners. This requires teaching and learning scholarship.

This article has discussed the innovative way in which a mixture of various technologies has been trialled. Some have been successful while others still require refining. However, it is also inevitable to face resistance to the implementation of e-learning technologies which requires changes to the traditional systems of educational institutions. It has been shown that the relationship between age and adoption of technology was mediated by cognitive abilities, computer self-efficacy, and computer anxiety (Czaja et al 2006). For this kind of change to be effective, evidence needs to be collected to demonstrate the favourable outcomes and the ease of implementation. This can be achieved

through survey based research showing successful incorporation of some of these technologies in teaching and learning of Health Science. The data collected from this research should also be used to convince the decision maker of universities and institutions to show the benefit of investing into multiple technologies for collaborative use.

CONCLUSION

In conclusion, e-learning is being increasingly embraced in tertiary education at numerous institutions and has gained approval from both the students and the teachers. Currently most of the e-learning tools are fragmented, incorporating just one or other technologies in class rooms. However, a standardised mix-mode of various online learning tools is required to cater for student from different socio-economic and educational backgrounds. At Griffith University the introduction of a mixed-mode of e-learning technologies including 3D virtual reality video, digital microscopy, Rpis, demonstration videos and e-portfolio has been demonstrated to be of effective educational value for students studying Medical Laboratory Science. In the future, studies should be performed to further evaluate the possible use of e-learning technologies in the education system and finding ways to convince the educators to embrace this mode of teaching and learning pedagogy. Finally, it is essential to standardise the use of education with maintenance of confidentiality and individuality to prepare graduates ready for global work force.

KEY TERMS AND DEFINITIONS

Cell Differentiation Counters: A counting tool used to count and tally different types of leukocytes.

Demonstration Video: A filmed video clip of a process or skill being performed for observation and review.

Digital Microscopy: The ability to view digital slides using a computer instead of a microscope.

E-Portfolio: A collection of electronic evidence assembled and managed by a user, usually on the Web. They are becoming standard practice for academics, students, and professionals and typically include examples of skills and achievements, as well as a reflective blog element.

Medical Laboratory Science: A four year undergraduate course in the field of medical science diagnostics and pathology.

Mix-Mode Learning: The use of technology to replace some of the face to face teaching with technology mediated learning tools.

Problem Based Learning (PBL): A student centred interactive learning pedagogy that challenges students to learn through engagement in a real life problem.

Raspberry Pi: A credit card sized computer that uses Linux Operating System.

Self-Directed Learning: Individuals perform their own study in an un-facilitated environment.

Simulations: A program or external setting that mimics an event or process, where participants can re-enact the process outside of a real-time event.

Tertiary Education: All post-secondary school education including but not limited to universities.

INTRODUCTION

The need for reforming the delivery of healthcare services to accommodate the needs of modern societies is being experienced on a global scale. Government expenditure for the healthcare domain is increasing on a yearly basis (Bergamo, 2015). Population figures are growing with a reported increase of one billion people within the next 15 years, reaching 8.5 billion in 2030 (UN, 2015). Such a rapid increase in population is placing pressure on existing resources for healthcare (Keehan et al., 2015), thereby stressing the need for healthcare services to be reformed. Within the rapid rates of population growth, the fastest growing segment in the European population is the over 65 age group (Coale and Hoover, 2015), a group which utilises three to five times more healthcare services than their younger counterparts. Additionally, disease growth is on the increase as population rates incline. Despite the major progress in reducing death rates from various diseases, dramatic changes in global diseases have occurred whereby diseases have shifted to more lifestyle-related diseases (e.g. obesity, chronic obstructive pulmonary disease, type 2 diabetes and heart disease). Issues such as expenditure, population and disease growth enhance the need to reform the delivery of healthcare services. It is recognised that Information Systems (IS) is a critical success factor in the achievement of health care reform goals (Heeks, 2006) as the general use of IS globally is a powerful driver for change across

the healthcare industry. Advantages of successfully implementing IS within the healthcare domain are reported in literature. These include reduced time to diagnosis, improved access for patients to care, quality of life and patient satisfaction, enhanced healthcare provider decision making, increased accuracy in medical treatment and cost-savings (Bergamo, 2015).

Hospital Information Systems (HIS) were the main and earliest use of IS in healthcare (Reichert, 1975). Prior to 1960, electronic computers were not in general use in hospitals (Austin and Greene, 1978). From these early days HIS were defined as systems for “transmitting data among various personnel in different support units of the hospital” which ultimately seeks to “integrate all elements of information processing related to patient care into one system with a shared database” (Barnett and Zielstorff, 1974, p. 158). This definition of HIS has been used as a guide to defining the various eHealth technologies which subsequently emerged. However, since the 1970s HIS have evolved by incorporating other types of eHealth technologies, e.g. electronic medical records or electronic health records (EHR), electronic clinical decision support systems (CDSS), which has resulted in the varying definitions we observe in literature today.

Building from this, the objective of this paper is to define and characterise the landscape of eHealth technologies from an Information Systems (IS) perspective. The next section defines and characterises the concept of electronic Health (eHealth).

In doing so, various features and functionalities of eHealth technologies are reported. It is argued that the evolving nature of technological artefacts influence how the term eHealth is defined. In light of this, the concepts of eHealth integration and ontologies are subsequently discussed. Concluding this chapter is an overview of both academic and practitioner-orientated contributions and future eHealth research directions.

BACKGROUND

Although the term electronic health or ‘eHealth’ first emerged in the literature circa 1999-2000 (Eysenbach, 2001; Ahern et al. 2006) the use of IS within the healthcare system occurred well before then (Blum, 1984). According to Goldschmidt (2005) the first electronic health record was designed and deployed in the late 1960s-1970s, thirty to forty years before the term eHealth was coined. Since the turn of the 21st century the term eHealth has received attention in both academia and practice. Subsequently, eHealth has been defined by many people but a lack of evidence as to the existence of a comprehensive definition has emerged (Della Mea, 2001; Oh et al., 2005; Pagliari et al., 2005; Boogerd et al., 2015). To address this issue, journals such as “Journal of Medical Internet Research” published papers which explicitly sought to clarify what is meant by eHealth (cf. Oh et al., 2005; Pagliari et al., 2005) as part of its “What is eHealth” series leading to various reports about definitions concerning eHealth. For example for Ontario Hospital eHealth Council, eHealth is a consumer-centred model of health care where stakeholders collaborate, utilising ISs, including Internet technologies to manage health, arrange, deliver and account for care, and manage the health care system (Alvarez, 2002). The Internet clearly drives the development and adoption of eHealth applications; standing alone, it has the reach, the infrastructure, and the acceptance to achieve widespread change. Similar to this definition, Eng (2001) describes eHealth as the utilisation of emerging IS, especially the Internet, to improve or

enable health and healthcare. While many definitions for the term eHealth were proposed, it was the work of Della Mea (2001) which received the most attention as he described eHealth as a broad term that encompasses multiple domains (Boogerd et al., 2015). Over ten years later, and due to the rapidly changing field of eHealth, Boogerd et al., (2015) argues that a clear, uniform definition for eHealth still remains to be identified with many terms (such as Medicine 2.0, Health 2.0, mHealth) being used interchangeably.

For the purposes of this paper, eHealth is expressed as an umbrella term which encompasses three domains (i.e. business, clinical and consumer). According to DeLuca and Enmark (2000) business eHealth refers to systems focusing on financial and administrative transactions required to conduct the daily operations of healthcare whereas clinical eHealth refers to systems focusing on transactions which involve the collection, transmission and analysis of electronic health-related data by healthcare professionals. Consumer eHealth engage patients (i.e. consumers) in managing their own health care, to facilitate communication with providers and social networks, meeting their informational needs, making knowledgeable health decisions, using patient education resources, and promoting healthy lifestyles (Kreps and Neuhauser, 2010). Building from this, eHealth is defined as “*the use of any information technology by various stakeholders which transmits, stores, searches, and/or retrieves digitised data electronically for business, clinical and/or consumer purposes*” (adapted from De Luca and Enmark 2000; Della Mea, 2001). Further, the World Health Organisation (WHO) defines eHealth as “the transfer of health resources and health care by electronic means... encompasses three main areas: (1) The delivery of health information, for health professionals and health consumers, through the Internet and telecommunications; (2) Using the power of IT and e-commerce to improve public health services, e.g. through the education and training of health workers; (3) The use of e-commerce and e-business practices in health systems management. This

definition of eHealth is diagrammatically represented in Figure 1 and illustrates that eHealth (sometimes referred to in literature as Medicine 2.0 or Health 2.0) is an overarching term for the use of IT within the healthcare domain and comprises several subsections. Table 1 briefly synthesises fourteen eHealth subsections (i.e. technologies), associating them with at least one of the three domains. Note this is not an exhaustive list.

Information Systems (IS) research is typically characterised by the three pillars of People, Process and Technology (Earl, 1989). Figure 1 represents all three facets of IS identifying (1) the various stakeholders/*people* involved within the eHealth domain (i.e. government/policy makers, health insurers, software vendors/developers, patients/citizens, healthcare providers and NGOs); (2) business, clinical and consumer *processes* associated with eHealth and (3) sample *technologies* (i.e. desktop, mobile, wearable IT and 3D printing) used to collect, store, retrieve, and analyse medical-related data/information. Therefore, eHealth goes beyond technology to focus on further understanding the role of people and new models of care within the health care domain (Wyatt and Sullivan, 2005).

Table 2 presents some of the commonly referenced definitions by academics and practi-

Table 1. Various eHealth Technologies

eHealth Technologies	Domain
1. Clinical Decision Support System (CDSS)	Clinical
2. Computerised Physician Order Entry (CPOE)	Business
3. Critical Test Result Management (CTRM)	Clinical
4. Electronic Health Record (EHR)	Clinical/Consumer
5. Electronic Medical Billing (EMB)	Business
6. Electronic Medical Record (EMR)	Clinical/Consumer
7. ePrescription (eRx)	Clinical
8. Healthcare IS (HIS)	Clinical/Consumer
9. Medical and Patient Scheduling Software (MPSS)	Business
10. Picture Archiving and Communication System (PACS)	Clinical
11. Patient Portal (PP)	Consumer
12. Patient Health Records (PHR)	PHR
13. Real Time Location System (RTLS)	Business
14. Telehealth/Telemedicine (TH/TM)	Clinical/Consumer

tioners for well-known and widely used eHealth technologies. While a general consensus exists for defining some eHealth technologies there remains inconsistencies in defining EHR, EMR and PHR.

Figure 1. Overview of eHealth

Table 2. Definitions of eHealth Technologies

Type	Definitions
CDSS	“any program designed to help healthcare professionals make clinical decisions” (Musen et al., 2001, p. 575) “any electronic system designed to aid directly in clinical decision making, in which characteristics of individual patients are used to generate patient-specific assessments or recommendations that are then presented to clinicians for consideration” (Lobach et al., 2012).
CPOE	“a process that allows a physician to enter medical orders directly and to manage the results of these orders” (Aarts et al., 2007, p. S4) “a computer application healthcare providers use to enter orders for medications, diagnostic tests, and ancillary services into a computer system. The EMR refers to a computerized record of patient data” (Dykstra et al., 2009, p.158)
CTRM	“also known as Critical Test Results Reporting, and Closed-Loop Reporting, is the software that handles a medical test result that has returned as critical to a patient’s health. It prevents the critical result from being lost in communication failures, improves patient safety, and documents the delivery of the results.” (MedicExchange, 2015)
EHR	“digitally stored healthcare information about an individual’s lifetime with the purpose of supporting continuity of care, education and research, and ensuring confidentiality at all times” (Lakovidis, 1998, p.106) “a paperless form of a patient’s medical record where HCPs [Healthcare providers] can enter and retrieve information utilizing a computerized system rather than writing in a paper chart” (Wallace et al., 2012, p.34)
EMB	.. allows interaction between payers/insurance companies and healthcare providers/organizations, managing payment for healthcare services (MedicExchange, 2015)
EMR	“an electronic health record that shares data only within its organization” (Bryne et al., 2010, p.637) “the health record used to gather, store, retrieve, and analyze medical information (Richards et al., 2012, p.121)” “synonymous with EHR” (Duncan, 2015, p.12)
eRx	“entering a prescription for a medication into an automated data entry system, and thereby generating a prescription electronically, instead of handwriting the prescription on paper” (Kilbridge, 2001, p.9) .. entire process of prescribing a medication in electronic format whereby the clinician prescribes medications which is then sent electronically to a pharmacy, and feedback comes back to the clinician when the patient collects the prescription (Cusack, 2008)
HIS	Includes all the elements that facilitate the capture, storage, processing, communication, security, and presentation of computer-based patient record information (Janczewski and Xinli Shi, 2002) “a comprehensive, integrated information system designed to manage the administrative, financial and clinical aspects of a hospital which encompasses paper-based information processing as well as computerised data processing” (Ismail et al., 2010, p.16).
MPSS	“provide intelligent scheduling system applications for healthcare practice, and let the care provider manage/schedule patient appointments through electronic preference cards” (MedicExchange, 2015)
PACS	..medical imaging technology which provides economical storage, rapid access to images from multiple modalities and simultaneous access to the same image at the one time (Choplin, 1992). “a computerised means of replacing the roles of conventional radiological film: images are acquired, stored, transmitted, and displayed digitally” (Strickland, 2000, p.82).
PP	... an internet-based interactive website for patients to communicate with their healthcare provider and with varied functions that gives them access to portions of their medical record and other services (Collmann and Cooper, 2007; Hess et al., 2006; Lin et al., 2005; Sorensen et al., 2009).
PHR	“provider-tethered applications that allow patients to access health information that is documented and managed by a health care institution” (Bourgeois et al., 2009, p.65). “is owned and controlled by the individual patient (or proxy), and may have information that is not contained in a medical record” (Emont, 2011, p.2).
RTLS	.. uses real time tracking to “enhance oversight on an array of hospital owned equipment/items. (MedicExchange, 2015).
TH/TM	“delivery of health care and sharing of medical knowledge over a distance using telecommunication system” (Thrall and Boland, 1998, p.145) “a service where clients’ vital signs are monitored remotely, at pre-set time intervals, using technology in their home” (Cartwright et al., 2011, p.6)

In order to fully appreciate how the eHealth technologies are defined (see Table 2), it is imperative to explore the characteristics (i.e. features and functionality) of the technologies. For the purpose of this study, we have focused on five key eHealth technologies namely, EHR, EMR, OHR, eRx and CDSS in Table 3. In order to identify the features and functionalities of the technologies the authors (i) reviewed three sources of the top ten eHealth technologies, (ii) identified five consistently named technologies across the lists, (iii) reviewed the selected technologies, and (iv) identified key features/functionalities. It is important to note that the core features and functions of eHealth technologies were captured as some technologies had 100+ features/functionalities.

Eng (2001) embraces 5 C's which seek to express eHealth functions and capabilities including: content, connectivity, community, commerce and care. Eysenbach (2001) identifies with 10 essential E's: efficiency, enhancing quality,

evidence-based, empowerment, encouragement, education, enabling, extending, ethics, and equity. Overtime, various features and functions have been incorporated within eHealth technologies which may account for the changing nature of defining eHealth technologies. Roberts and Grabowski (1990) refer to technological growth and argues that definitions for technological-related artefacts are not static but in fact evolving overtime. This may account for the varying definitions which have emerged for eHealth technologies over the last decade. It is further evident from Table 2 and from the definitions off the various eHealth technologies (Table 3) that there is a need to integrate the various features and functions of eHealth, as advocated by Eng since 2001.

Table 3. eHealth Technologies Features/Functionalities

eHealth Technologies	Basic Features	Basic Functions
EHR/EMR/PHR	• Patient management • Symptom management • Medication management • Note management • Results retrieval • Order entry • Report generator	• Identify and maintain a patient record • Manage patient demographics • Manage problem lists • Manage medication lists • Manage patient history • Manage clinical documents and notes • Capture external clinical documents • Present care plans, guidelines, and protocols • Manage guidelines, protocols and patient-specific care plans • Generate and record patient-specific instructions
eRx	• Patient management • Symptom management • Medication management • Order entry • Formulary management • Electronic Refills	• Identify and maintain a patient record • Manage patient demographics • Manage medication lists • Manage patient prescription history • Check drug interactions • Send and approve prescriptions
CDSS	• Patient management • Symptom management • Medication management • Reminder notification • Recommended diagnosis and treatment	• Manage patient demographics • Manage problem lists • Manage medication lists • Enhance diagnostic accuracy • Assist with clinical decision making • Improve patient safety

* Sources of Features/Functionalities

EHR/EMR/PHR: 1. Allscripts, 2. Athenaclinicals, 3. ClinicalWorks, 4. CareCloud, 5. PracticeFusion.

eRx: 1. Allscripts, 2. HealthFusion MediTouch, 3. NueMD, 4. PracticeFusion, 5. SureScripts.

CDSS: 1. EBMeDS, 2. IndiGO, 3. Mantis, 4. Persivia, 5. Zynx Health.

FUTURE RESEARCH DIRECTIONS

Integration has been the Holy Grail of Management Information Systems since the early days of computing in organizations. (Kumar and van Hillegersberg, 2000, p.23)

Integrated health systems are widely advocated to enhance performance in terms of quality and safety as a result of effective communication and standardised protocols (Suter et al., 2009). With the diffusion of the Internet and other information and telecommunication technologies, more integration has been enabled and demanded (Braa et al., 2007). In a healthcare context, Simoens and Scott (2005) argue that integration is integral to offering services from primary through tertiary care. The basis of integration is characterised by cooperation (O'Leary-Kelly and Flores, 2002), coordination, collaboration (Ettlie and Stoll, 1990; Kahn and Mentzer, 1998), information sharing (Pagell, 2004) and a fundamental shift away from managing individual functional processes, to managing integrated chains of processes (Akkermans et al., 1999). Building on this, it is therefore imperative that future eHealth developments move away from vertical silos to horizontal integrated systems (Adenuga et al., 2015) to ensure that a standardised delivery of care is provided (Simoens and Scott, 2005; Suter et al., 2009).

To facilitate a standardised and holistic delivery of health care services it is imperative that eHealth technologies are integrated across the three levels of delivery (Adenuga et al., 2015). These levels include primary care, secondary care, tertiary care (Reynolds, 1975). Primary care is defined as a set of universally accessible first-level contact, continuous, comprehensive, and coordinated care (Starfield, 1994) that promote health, prevent disease, and provide diagnostic, curative, rehabilitative, supportive, and palliative services (Lamarche et al., 2003). While, secondary care is a short term referral provided by informal consultations of secondary-care physicians with primary-care physicians (Starfield, 1994) to patients with symptomatic stages of a disease(s)

who require moderately specialised knowledge and technical resources for adequate treatment and/or rehabilitation (Reynolds, 1975). Often health services delivered at secondary care lead to referrals for tertiary care. According to Reynolds (1975), this function encompasses levels of diseases which are acutely threatening the health of the individual and require highly technical and specialised knowledge, facilities and personnel. Integration of eHealth technologies is important because of the highly interrelated nature of the functions that are performed across primary, secondary and territory levels in the provision of patient care (Austin and Greene, 1978).

Table 3 indicates that the eHealth technologies available within the healthcare system share common features and functionalities. In order for the seamless integration of these, eHealth developers need to embrace multiple ontologies (sometimes referred to as Medical Natural Language Processing) that can be combined to fully realise meaningful integration and analysis of data in the healthcare domain (Puri et al., 2011). An ontology, according to Stabb and Studer (2013), is a description (like a formal specification of a program) of concepts and relationships that can exist for an agent or a community of agents. The concept is important in terms of building a common language for the purpose of enabling knowledge sharing and reuse, which is integral for a standardised delivery of healthcare (Nardon and Moura, 2004).

The healthcare sector is criticised for the proliferation of terminologies across medical specialities, locales, health care facilities, and it also with clinical content (Shoniregun et al., 2010). Overcoming this challenge is reported to have numerous benefits for the healthcare sector. For example, the development and use of widely understood and accepted ontologies can build more powerful and more interoperable IS in healthcare (Kim and Chung, 2014) by facilitating the easy transfer and re(use) of patient-related data (Lucas and Bulbul, 2015). Moreover, it will promote a 'big data' environment which could be used to analyse trends/patterns in large data sets thereby

generating new insights in the medical domain (Dung and Kameyama, 2007; Bodenreider, 2008). Big data in healthcare denotes large and complex electronic health datasets which are perceived to be difficult (or impossible) to manage with traditional data management tools (Kołodziej et al., 2015).

According to Raghupathi and Raghupathi (2014, p. 2) 'big data' in a healthcare context amalgamates clinical data from CPOE and CDSS (physician's written notes and prescriptions, medical imaging, laboratory, pharmacy, insurance, and other administrative data); patient data in EHRs; machine generated/sensor data (e.g. vital sign monitoring), social media posts (e.g. Twitter) and web pages and less patient-specific information, including emergency care data, news feeds, and articles in medical journals. Therefore, integrated eHealth technologies with consistent ontologies will enable the creation of 'big data' for health care scenarios thus, enabling the discovery of associations and understanding of patterns and trends within the datasets for diagnosis, prognosis and treatment of illness and enhanced understanding of healthcare resource distribution (Arima, 2016).

CONCLUSION

There has been a surge of electronic health (eHealth) technologies encompassing a range of services available to various stakeholders within the health care system in both developed and developing countries. The advantages of successfully implementing eHealth technologies are reported in literature. Research indicates that these advantages significantly outweigh the heavily criticised costs associated with introducing such technological artefacts. As technology has evolved, the features and functionalities offered by eHealth technologies have grown dramatically leading to the development of many advanced technical solutions intended to serve various stakeholders (e.g. patients, clinicians, administrators). Additionally, the use of mobile telecommunications enables the use of eHealth at the point-of-care moving beyond its previously restricted desktop environments. Ex-

amples include Electronic Health/Patient Records, ePrescribing and Clinical Decision Support tools. As a result of this increased focus on eHealth, conflicting definitions for what constitutes the term eHealth have emerged in the literature. This lack of consensus is further inhibited by a dearth of research documenting the characteristics (i.e. features and functionalities) of such eHealth technologies. Given the nascent nature of eHealth research and the lack of definitional convergence, we define and characterise the landscape of eHealth technologies from an Information Systems (IS) perspective. Embracing this perspective provides a more detailed overview of the eHealth landscape. By examining existing literature and reviewing the market place, this paper reveals that there is a need to integrate the various features and functions of eHealth technologies thereby arguing that integration and interoperability is important for the growth of eHealth resulting in a more holistic approach to eHealth. Thus providing comprehensive coverage and up-to-date definitions of one of the most important issues, concepts, trends and technologies in information systems (IS) and information technology (IT); namely, eHealth.

There will be more changes in the future within the eHealth domain given how rapidly technology has evolved over the last two decades. With this in mind, eHealth definitions should be broad and flexible (i.e. modifiable with the changing components associated with new technologies). That being said, in defining eHealth it is essential that a common vocabulary (ontology) is developed and used to support the information needs of the various stakeholders, i.e. healthcare professionals and patients, while keeping standardisation and integration at the core of efficient and effective eHealth solutions.

Not only does this work contribute to the academic community, it also benefits practitioners in the decisions they make regarding eHealth technologies and the establishment of best practice in the form of eHealth standards and policies in the future.

KEY TERMS AND DEFINITIONS

eHealth Technologies: The umbrella term used to describe the wide variety of technologies, including internet based services, that support a health care system.

eHealth Technology Feature: Defines the purpose(s) of an eHealth system e.g. patient management, patient report generation.

eHealth Technology Functionality: An individual behaviour of an eHealth system e.g., identify and maintain patient record.

eHealth: The provision of patient-centric care and related services (i.e. people and processes) supported by technology.

Information Systems: The use of people, process and technology to get the right information to the right people at the right time.

Integrated Health Systems: Technologies that are characterised by their ability to cooperate, collaborate and communicate with other technologies.

Ontology: A set of agreed rules, usually in the form of a common vocabulary and relationships, used to enable the transfer of data/information/knowledge between two or more agents.

Kinect Applications in Healthcare

Roanna Lun

Cleveland State University, USA

Wenbing Zhao

Cleveland State University, USA

INTRODUCTION

Microsoft Kinect is one of the most popular inexpensive gadgets released in recent years. Kinect is equipped with a color camera, a depth camera, and a microphone array. The device allows users to interact with a computer via a natural user interface in terms of gestures or voice commands. So far, Microsoft has released three versions of Kinect sensors. The first two, typically referred to as Kinect for Xbox and Kinect for Windows, are rather similar except that Kinect for Windows is capable of doing near-mode tracking. Because both releases use the same depth sensing technology, they are collectively referred to as Kinect version 1, or Kinect v1 for short. The most recent Kinect sensor was released together with the new game console, Xbox One. Hence, it is sometimes referred to as Kinect for Xbox One. It uses a completely different depth sensing technology, which is based on time-of-flight measurement. As such, the new sensor is also referred to as Kinect version 2, or Kinect v2 for short. Kinect v2 has made drastic improvements over Kinect v1, including 1080p resolution for the color camera, and higher actual depth sensing resolution (the nominal resolution for the depth sensing resolu-

tion is actually lower than that for Kinect v1). Images of the two versions of Kinect sensors are shown in Figure 1.

The low-cost and the availability of Software Development Kit (SDK) for Microsoft Kinect \ has attracted many researchers to investigate its applications in many areas, particular in the healthcare realm. As the aging population rapidly grows in the United States, demands of healthcare services, especially physical therapy and rehabilitation services, have grown enormously in recent years. To meet the increasing demands and reduce the cost of services, providers are often looking for computers and other equipment that can assist them in providing services to patients in an affordable, convenient, and user-friendly environment. As a low-cost, portable, accurate, nonintrusive, and easily set up motion detecting sensor, Kinect enables researchers to develop computer-based vision control without using traditional input devices, e.g. mouse, keyboard, or joystick. This revolutionary technology makes it possible for Kinect to meet the challenge of providing high quality evaluations and interventions at an affordable price for healthcare services, as seen from the works surveyed in this chapter.

Figure 1. Two versions of Microsoft Kinect sensors. On the left is the Kinect v1. On the right is the Kinect v2.

DOI: 10.4018/978-1-5225-2255-3.ch511

BACKGROUND

Microsoft Kinect provides several streams of information to a software developer. The most common streams include: (1) A stream of 2D color image frames; (2) A stream of 3D depth image frames; and (3) A stream of 3D skeletal frames for at least one human subject in the view. A skeletal frame may contain the 3D position information for various number of joints. The availability of the skeletal frames has greatly facilitated Kinect application development because it frees the application developers from dealing with the complicated task of human pose estimation.

In Kinect v1, the depth of each pixel is calculated via a structured light method, which enables the use of a single infrared (IR) emitter and a single depth sensor to calculate the depth of each pixel. While this is a very clever scheme, the fidelity of the depth measurement is quite low because for the depth sensing to work perfectly, there has to be a

visible unique pattern for each pixel. Because there has to be some space between two adjacent dots as part of the structured light and this space has to be wide enough for the depth sensor to distinguish, only about 1 in every 20 pixels has a true depth measurement in typical situations and the depths for other pixels must be interpolated. Hence, the depth sensing resolution is actually significantly below the nominal 640x480 for Kinect v1. The depth-sensing technology used in Kinect v2 is completely different and the depth is calculated based on time of flight. The depth of each pixel can be calculated based on the phase shift between the emitted light and the redirected light.

Due to the maturity of the Kinect technology, developers can now publish Kinect v2 applications to the Windows store. Kinect v2 SDK also provides oial support for Unity, which is a development platform for 3D games. Finally, Kinect v2 SDK provides a tool to develop gesture recognition based on machine learning.

APPLICATIONS REVIEW

In this section, we review the applications of the Kinect technology in a number of healthcare domains. A summary of the applications is provided in Table 1. The detailed description of the applications is given in individual subsections.

Physical Therapy and Rehabilitation Applications

Kinect has been widely used in physical therapy exercises, sports rehabilitation processes, and post-surgery training. Research has proved that Kinect can be a viable physical rehabilitation tool. Compared to traditional motion tracking and capturing programs that use reflective markers attached to users' bodies, the Kinect technology enables the development of solutions with noninvasive natural user interfaces and with real-time visual feedback to users.

Using Kinect's interactive interface could get patients more motivated and engaged in physical activities, particular for regular and repetitive movements in physical rehabilitation exercises. Chang, Chen, and Huang (2011) developed an interactive Kinect-based system to assist therapists in rehabilitating students in public school settings. The system is able to detect the student's joint position, and record movement data to allow therapists to review students' rehabilitation progress quickly. It also includes an interactive visual interface to enhance students' motivation, interest, and perseverance to engage in physical rehabilitation. The result has demonstrated that Kinect's natural interactive visual computer interface can significantly attract more users. In the study of real-time gesture recognition, Bigdelou, Benz, Schwarz, and Navab (2012) concluded that most users are fond of the dynamic interaction with system. Applications using Kinect technology are overwhelmingly regarded as friendly visual interaction programs.

A research group at the University of Southern California Institute for Creative Technologies

(ICT) has successfully applied the Kinect device to the study of virtual reality simulation technology for clinical purposes. Through extensive evaluation, assessment, and analysis, the researchers at the ICT have shown that Kinect technology can make a major contribution to the quality of traditional intervention with computer-based training games specializing in mental health therapy, motor skills rehabilitation, cognitive assessment, and clinical skills exercises. Lange et al. (2011) developed a virtual reality simulation game used for balance training of adults with neurological injury. Their colleagues Suma et al. (2011) developed the Flexible Action and Articulated Skeleton Toolkit, which is middleware that facilitates integration of full-body control with virtual reality applications and video games using Kinect.

Focusing on cognitive rehabilitation for Alzheimer patients, Cervantes, Vela, and Rodríguez (2012) developed a video game that replaces the traditional techniques used by therapists with the natural interaction Kinect device. The interactive body-motion controlled game increases patients' motivation to participate in exercise. An interactive rehabilitation system for disabled children was developed by Rahman et al. (2013). This application allows activities to be synchronized with on-line virtual counterparts. Patients can follow the exercise at home in the absence of the therapist because visual guidance for correctly performing the exercise is provided. Gotsis et al. (2012) demonstrated a mixed reality game for upper body exercise and rehabilitation. The exercise protocol was adopted from an evidence-based shoulder rehabilitation program for individuals with spinal cord injury.

Metcalf et al. (2013) studied an application for real-time monitoring and assessing hand movement based on Kinect. Hand rehabilitation is often needed for stroke patients' recovery. Medical professionals require detailed and accurate measurement of the hands in order to assess progress and functional recovery. The system is capable of measuring finger joint kinematics in real time for home-based clinical rehabilitation

programs. This system is designed in two steps: 1) identify anatomical landmarks and classification between grip types; 2) calculate hand joint angles from a kinematic model. The initial phase detects two different modes: spread hand mode and pincer grip mode. Then the landmarks go through validation procedures first by using ground truth estimation between reviewers and the associated algorithms to assess the accuracy of landmark definition, and second by joint angles compared to a laboratory-based gold standard motion capture system and validated kinematic measurement technique. And on the other side, patients require real-time feedback on their hand posture if they participate in a virtual environment rehabilitation gaming platform. Although this novel technique can robustly track and accurately measure the movements of the hand, it only provides a limited number of gestures that are only suitable for a specific rehabilitation application.

In order to reinforce the quality of home-based real-time rehabilitation exercise, Su (2013) proposed an approach using the Dynamic Time Warping (DTW) algorithm and Fuzzy Logic for ensuring that exercise is performed correctly. First it allows a patient to perform a prescribed exercise in the presence of a professional. Then the patient's exercise is recorded as a base for evaluation of exercise at home. The outcomes of the evaluation can be used as a reference for the patient to validate his/her exercise and to prevent adverse events. A summary report of the outcomes may also be uploaded to a cloud setting for physicians to monitor progress and adjust the prescription. The DTW algorithm is used to compare two sequences that have different time lengths in order to determine the similarity between the standard and the patient's exercise movements. For the rehabilitation exercise, the trajectory and speed mainly are based on experience and subjective evaluation. Therefore traditional logic theory is not practical for evaluating the quality of rehabilitation exercise by trajectory and speed. In this application, Fuzzy Logic is employed to build a fuzzy inference of a physician's subjective evaluation.

Saini et al. (2012) presented an approach to providing stroke patients with instruction and guidelines to perform rehabilitation exercises. A “watchdog” developed in this system provides the restriction that patients cannot exceed the limited angle, and ensures that a patient who is exercising at home will not exceed the prescribed level or perform for a longer period than necessary. A centralized system stores the entire patient's data that will be used to analyze the patient's movements and activities. The biofeedback system allows the user to give feedback to the therapist, and the therapist will evaluate the patient's movement and give further instruction or direction. The biofeedback is displayed for the patient as well as the therapist. The main benefit for biofeedback is that patients can directly communicate with the therapist for further instruction for improving their movements. This strategy is beneficial for stroke patients because patients will do exercises correctly.

Recently, Zhao et al. (2014a) developed a Kinect-based system that could be used at patient's home. In addition to providing visual guidance to patients regarding how to perform a prescribed rehabilitation exercise correctly, the system is capable of assessing the quality of the exercise in realtime based on a set of correctness rules (Zhao et al., 2014b).

Clinical Environment Applications

A key technical challenge using Kinect in clinical environment, e.g. in a medical operating room, is how to recognize the gestures interactively, accurately, robustly, and effectively. Touch-free interaction with a computer makes the Kinect device suitable for clinical environments in highly sterile conditions (Johnson et al., 2011). Their study showed that the touch-free motion recognition Kinect device provides an appealing opportunity to control medical images or image-guided devices without using the hands. Some researchers investigated gesture recognition systems based on the Kinect technology to address needs in medical surgical rooms.

Gallo, Placitelli, and Ciampi (2011) developed an open source interface using static postures and dynamic gesture recognition techniques to explore CT, MRI, or PET images in operating room. Utilizing hand and arm gestures, this application is able to execute basic tasks such as image selection, zooming, translating, rotating, and pointing; and some complex tasks, e.g. manual selection for controlling medical digital images effectively. The interaction follows the event – state – action paradigm and it is developed specifically for fast operation at video frame rates. The limitation of this interface is that the number of postures and gestures used for recognition is fixed. The extension of the gesture control interface to enable interaction with immersive medical imaging environments must be addressed in future development.

Bigdelou et al. (2012) applied Kinect 3D gesture-based interface technology to an intra-operative medical image viewer in a surgical environment. They used skeleton input to recognize the gesture type and the relative poses within that gesture. The recognized gesture and poses can be used for an interface for controlling a medical image viewer. The training phase is used to define and customize gestures from skeleton images, and during the interaction phase, the actual gesture and the relative pose within the gesture is estimated by discriminative kernel regression mapping. The quantitative experiments show this method can simultaneously recognize several gestures to a high degree of accuracy. Again, the number of gestures recognized is limited to 16 due to computational complexity for human body movement.

Fall Detection Applications

The Kinect device has been used as a real-time fall monitoring and detection system for a wide range of falls, including backward, forward, and sideways; on stairways; in occlusion places; in hospital wards; and others.

In a study of detecting human body falling motion, Mastorakis and Makris (2014) adopted the use of Kinect depth images instead of skeleton

data to robustly and efficiently track body motion. In their approach, a fall is detected by analyzing the 3D bounding box's width, height, and depth, i.e., the width, height, and depth of the human posture. The algorithm is provided by OpenNI. This approach outperforms the articulated model, which requires significantly more computational power. Since a human fall is a fast activity, a high frame rate in real-time systems is required to avoid missing detections. Furthermore, this algorithm has proved stable and can even detect movement when half of the subject's body is occluded by surrounding objects. Bian, Chau, and Magnenat-Thalmann (2012) presented an algorithm to improve the accuracy of skeleton extraction by rotating the human body trunk based on the pose in the previous frame.

Obdrzalek et al. (2012) presented a method that the accuracy of body tracking to a great extent depends on the type of poses being observed, the distance from the sensor and possible occlusions. They conducted a data acquisition process from captured human poses using the marker-based motion capture system developed by Microsoft Kinect. The result shows that Kinect works with much denser but less precise 3D data comparing to the marker-based system. They also observed that the markerless skeleton tracking of Kinect depends solely on dense depth information and thus frequently fails due to occlusions. For physical exercise of the elderly population, the Kinect skeleton tracking struggles with occluding body parts or objects in the scene, e.g. a chair. The occlusion is indeed an open issue for the use of Kinect technology in healthcare applications.

In the research work of Parra-Dominguez, Taati, and Mihailidis (2012), a method particularly to detect falls and other abnormal events on stairs was proposed. This work can automatically estimate the walking speed and extract a set of features that encode human motion during stairway descent.

Ni, Nguyen, and Moulin (2012) developed a computer vision based system to prevent potential falls in hospital ward environments. This system is

able to automatically detect the event of a patient getting out of a bed. The nursing staff is alerted immediately to provide assistance once the getting up event is detected. The detection algorithm combines multiple features from multiple modalities via an MKL framework to achieve high accuracy and efficiency.

Rougier et al. (2011) introduced an approach to address occlusion for detecting human body falls. The method is based on human centroid height relative to the ground and body velocity. With the help of computing 3D personal velocity just before the occlusion, this method can accurately detect falls by measuring human centroid height, because the vast majority of falls end on the ground or near the ground.

Zhang et al. (2012) proposed a system that employs two Kinect sensors to detect human falls. The statistical method is based on information about how the person moves during the last few frames. The major contribution of this research work is that it collects all training data from a specific viewpoint, and then collects all the test data from a different viewpoint. They believe the new protocol is a useful approach for measuring the robustness of the system by spatial displacement of camera images. Stone and Skubic (2012) developed a system for capturing variation of stride-to-stride gait in home environments for elderly adults. By measuring the changes in gait, falls can be predicted. If the motion of joints of a specific body subject is detected in an unusual time sequence, the prevention message is generated as a caution.

FUTURE TRENDS

The algorithms used for processing images obtained from the Kinect device play a very important role for human body motion analysis in healthcare applications. In the study of automatically tracking and detecting abnormal events, Parra-Dominguez, Taati, and Mihailidis (2012) evaluated different

binary classification algorithms. Velloso, Bulling, and Gellersen (2013) suggested exploring more complex curve analysis techniques.

Although some existing applications already provide feedback for physical rehabilitation, there is still a huge range of possibilities of how this feedback may be improved (Velloso, Bulling, & Gellersen, 2013). The potential improvements could be multi-modal interaction, closer loop between the expert and the user, automated assessment, and so forth (Zhao et al., 2015).

Enhancing the entertaining and amusing elements of the system are possible for future improvement (Chang et al., 2011). It would make rehabilitation more enjoyable if more peers (or users) are engaged in rehabilitation activities simultaneously. Game-based exercises could increase patients' motivation for therapy (Saini et al., 2012). Continuously exploring 3D interaction techniques in virtual environments (Cervantes et al., 2012) will be the focus in the next generation for patients involved in physical exercise programs.

Home-based remote healthcare service might become the next generation for out-patient physical therapy and rehabilitation. With the development of advanced 3D sensors and cloud gaming software (O'Connor, Davy, & Jennings, 2013), it is very possible that more home-based rehabilitation training exercises will be available online (Rahman et al., 2013) or in a cloud server, which would be more convenient for professional therapists wishing to instruct, monitor, and assess patients' activities.

Most existing applications using Kinect technology in healthcare only apply to human upper body parts. The limited viewing range of the Kinect sensor has made it difficult to detect and track full body movements. In a study of automatically tracking and detecting abnormal events on stairs in elderly living centers, Parra-Dominguez, Taati, and Mihailidis (2012) discovered that tracking hip joint points from the skeleton frame in Kinect is more stable than tracking feet and ankles, due to the fact that feet and ankles are sometimes partially occluded from Kinect view. On the other hand, ap-

plications in healthcare services require full body motion analysis. Therefore, full-body detection is a critical challenge for the future development of Kinect applications in healthcare.

One of the main drawbacks of using Kinect skeleton in healthcare applications is that Kinect uses a very non-anthropometric kinematic model with variable limb lengths (Obdrzalek et al. 2012). In general postures, the variability of the pose estimation is about 10 cm. Future algorithms should address occlusions and self-occlusions, unconventional body postures, and use of wheel-chairs or walkers.

CONCLUSION

We believe that the research and development on using Kinect technology in healthcare will gain more momentum. The demand of Kinect-based applications is high, due to Kinect's low cost and portability, and its accurate and robust motion detection capability. In this chapter, we have surveyed the current applications of using the Kinect technology in healthcare. Furthermore, we outlined a number of open research issues that could overcome the limitations of the current Kinect technology.

KEY TERMS AND DEFINITIONS

Dynamic Time Warping (DTW): An algorithm for measuring similarity between two temporal sequences that may vary in time or speed. DTW calculates an optimal match between two given sequences (e.g. time series) with certain restrictions. The sequences are “warped” non-linearly in the time dimension to determine a

measure of their similarity independent of certain non-linear variations in the time dimension. This sequence alignment method is often used in time series classification.

Fall Detection: Detection of unexpected falls.

Fuzzy Logic: A form of many-valued logic. Fuzzy logic deals with reasoning that is approximate rather than fixed and exact. Compared to traditional true or false values, fuzzy logic variables may have a truth value that ranges in degree from 0 to 1. Fuzzy logic has been extended to handle the concept of partial truth, where the truth value may range between completely true and completely false.

Kinect SDK: A software developing kit released by Microsoft for the development of 3D sensing applications.

Randomized Decision Forest (RDF): An ensemble learning method for classification and regression that can operate by constructing a multitude of decision trees at training time and outputting the class that is the mode of the classes output by individual trees.

Rehabilitation Exercises: Exercises prescribed by a physical therapist to enhance the recovery of a patient after a surgery or certain diseases.

Virtual Reality: It refers to a computer-facilitated environment that simulates physical presence and allows the user to interact with the virtual world.

INTRODUCTION

Recently, in a continuously changing environment with a wide variety of trendy mobile or wearable devices, in an increasingly demanding market for additional benefits in favor of the end user, the success of a product depends on its ability to adjust to the needs and desires of the consumer. So, new concepts have emerged in spectacular pageantries for the amazed public eyes.

Within this scenic approach, the concept of Interface Design and Usability has come to surface not only for smartphones and tablets, which are definitely powerful computer devices, but also for a variety of wearable or implanted pieces of apparatuses that are in position to perform many of the functions of computing machinery.

Inevitably, the issue of Usability comes to surface, as it measures perhaps more clearly than any other factor, the ability of a product not only to affect the body but also the mind of the user. This seemed to be the situation experienced thus far only with advanced medical devices and prosthetics that enabled monitoring of subtle neurological functionality. Indeed, for diagnostic or therapeutic purposes microensors, wearable monitoring systems and various imaging assemblages provide an enhanced telecommunication channel between the actual patient organs and the monitoring clinician (Figure 1).

DOI: 10.4018/978-1-5225-2255-3.ch512

The initial success of implanted or portable devices used for health and fitness reasons has widely promulgated mobile device applications of all types that take advantage of the affordable imaging modalities, the immediate reporting potential, the endoscopic representations of computer generated signals, the tactile sensing, the microrobotic precision, the motion tracking, the stereotactic functionality, the GPS positioning, the accelerometer measuring of shock, vibration or orientation, and many others.

As microprocessor signal pins interface with the internal neurological architecture of the human organism, they synchronize external events with the structure and functionality of the brain. The notion of Usability, extensively used in Human Computer Interaction (HCI), refers to the potency of a product that is massively deployed to end users to bring into action specific targetable derivatives under certain circumstances (Dix et al, 2004). These are measured in terms of:

1. Effectiveness, i.e. the degree to which interaction with specific computing machinery is successful in producing desirable outcomes for particular activities or purposes.
2. Efficiency, that is the design of interaction in such a way so that the ratio of useful work performed to the total efforts attempted is maximized as possible.

Figure 1. Wearable and implanted devices used for detecting and ameliorating oral and aural communication. Left: video Frenzel goggles that eliminate vision and provide simultaneous eye movement recording for the Dix-Hallpike maneuver that detects Benign Paroxysmal Positional Vertigo. Center: Otologic Carina™ cochlear implantation deployed within the inner ear. Right: EEG cap recording brain activity produced by electroencephalography.

3. Subjective Satisfaction, which results from the fulfillment of a user's expectations or needs while using components of electronic equipment, or the whole apparatus collectively.
4. A feature that recently has become a key element in the use of electronic devices is Learnability, which has to do with prior acquired knowledge or skill in using equipment of some kind, whether this ability has been developed by study, teaching, experience or sociability. The last factor has emerged as a new attribute of computing experience out of the personal relation with social networking.

Although the first three factors give a more mechanically driven approach to the evaluation processes of HCI, it is the fourth element that has gained momentum in terms of business intelligence. Indeed, Learnability is crucial for consumer electronics, since users flock around products that have a User Interface (UI) metaphor, a paradigm or an idiom they have previously used (Rogers et al., 2011).

By this attitude, they commit much less burden into their memory and as a result they prefer modules that have well-established UI paradigms, as is for instance the Android operating environment and the iOS paraphernalia. Indeed, the smartphone market is a classic example of an advanced and multi potent computing environment that is used

globally, for really sophisticated and sometimes unconventional tasks that demand no prior formal education or training received (Nielsen & Mack, 1994; Nielsen & Budiu, 2012).

This fourth factor, when bad Interaction Design is endorsed, tarnishes the acceptance of new media accounting for them the reputation of being

- Infuriating
- Confusing
- Aesthetically unpleasant

It is exactly this attitude towards Interaction Design that makes the commercial products that come up from the medical aids arena to deploy not only a new aesthetic approach but also to seek a different endurance and a smart communication that co-exists within the user habits. Indeed, as UIs become more efficient and effective, they promote their usage as Brain Computer Interfaces (BCIs) as well (Figure 2).

BACKGROUND

Although the general public's pictorial perception for a BCI is mingled between the image of an EEG cap (an electrode studded cap that reads brain activity) and a portable device like Oculus Rift, in recent proceedings a more subtle schematic view has been emerging with devices like

Figure 2. A series of trendy commercial devices with advanced HCI capabilities: Left, Google Glasses®. Center, the versatile iWatch™ calculating the heart rate and not only. Right, the Oculus Rift fully immersive audio-visual device in conjunction with hand held controllers. A new brave world for extreme Virtual Reality experiences.

Cochlear Implants that transform input activity to brain activity (Politis et al., 2014).

Generally speaking, there are two kinds of BCIs (Dix et al., 2004):

1. Invasive

This category of products, undoubtedly the flagship of Interfaces, produce overwhelming immersion into what brain activity projects. In audio matters, such devices offer state of the art multi-track digital input capabilities and thus they simulate and gradually replace the sound input of the outside world. It is obvious that the hardwiring of Figure 3, image on the right, indeed resembles the

beginnings of electromechanical Interfaces. Subtle operations and engineering methods take place as any malfunction or any unguided penetration may induct erroneously the electrode into the posterior semicircular.

2. Non-Invasive

Not so immersive, they need some training via biofeedback, and their bandwidth is rather limited. They act more like assistive devices and do not totally replace a handicapped organ or instrument.

The focus of this article lies on how commercial gadgets play the role of what instrumentation does to medical technology in terms of augmentation.

As body parts are failing to function properly and restoration to a healthy state seems inefficacious, prosthetics are used to rehabilitate vital bodily functions. In the same sense, gadgets readily available to the wide public can increase the data flow from the outside world to the brain and vice-versa. This consideration, albeit promoted with niche computing machinery, comprises the central vision for the already over \$1 billion Blue Brain Project (Markram, 2006) and the Human Brain Project in Europe (Waldrop, 2012) that promulgate medical informatics and neuromorphic computing. The equivalent project on the other side of the Atlantic is the US-financed Brain Initiative (2013). These approaches, which rely heavily on data analytics and simulations, attempt to promote brain-inspired Information Technology (Amunts et al., 2016). As a result, interdisciplinary trajectories are motivated linking Neuroscience, Brain Medicine and Computer Science in pursuit of the complex links amongst cerebral activity and behaviour (Markram et al., 2015; NSF, 2006).

At this point HCI emerges: it is the interdisciplinary field that correlates many disciplines like engineering, psychology, computer science, industrial design, ergonomics, artificial intelligence, and more recently, sociology, anthropology, art sciences, etc.

So it is the technological advances in these fields, as far as mobile, wearable and implanted devices are involved, that provide a new potential for the quality of the UI (Nielsen & Budiu, 2012). Also, a new workflow framework is introduced which further progresses the functionality of computing devices that support oral and aural communication. Under this prism, HCI becomes more central to the design and development of augmented reality machinery, investigating functionality that did not previously exist for the user or functionality that was not virtually usable.

In strict terms a Cochlear Implant (CI) is an electronic device that restores partial hearing to individuals with severe to profound hearing loss; these people normally would not benefit from a conventional hearing aid. Conventionally, as the

American Academy of Otolaryngology (2015) puts it “it is surgically implanted in the inner ear and activated by a device worn outside the ear. Unlike a hearing aid, it does not make sound louder or clearer. Instead, the device bypasses damaged parts of the auditory system and directly stimulates the nerve of hearing, allowing individuals who are profoundly hearing impaired to receive sound” (Figure 3).

As stated earlier, the hardwiring of Figure 3, image far right, has a profound congruence with the origins of electromechanical Interfaces. Subtle operations and engineering methods take place as any malfunction or any unguided penetration may induct erroneously the electrode into the posterior semicircular canal damaging the facial nerve, or creating an unsupervised electrode contact within the vestibule. The implant consists of antenna, magnet, receiver stimulator in titanium casing, electrode array with electrode contacts, apical and basal, spaced at 2.4 mm intervals. The overall length of the implantable electrode array is 30 mm and its width 1.3 mm at the base and 0.8 mm at its apical end (Godara & Nikita, 2013).

Conclusively, a new generation of rather expensive gadgets transforms vigorous everyday activities: Google Glasses® consolidate with normal glasses, smart watches like iWatch™ display apart the others time and can dip into water, while contemporary fully immersive CIs disguise well with the scalp characteristics and allow their user even to swim. Either for medical purposes or for normal every day activities, computer aided infrastructures assists human senses to manipulate higher dimensional objects, which in mathematical terms leads to evading hyperspaces while in more pragmatic computer terms this directs users to virtual reality augmentations.

FROM PROSTHETICSTO BIONICS

Hearing disorders is the first pivotal point in disrupting the pipeline of proper oral and aural communication (Figure 4). They are quite common in

Figure 3. The Cochlear Implant pictorially: Left, the device, Cochlear's Nucleus Freedom™; Center: penetration and placement within the ear; Right, clinching the synapses of the audio nerve

modern societies not only due to congenital issues but also because diagnostic media are readily available. Hearing loss is perhaps the most common reason for visiting an ENT Department, both in the clinic and in the acute setting. As recent statistics reveal (Blackwell et al., 2014) approximately 15% of American adults (about 37.5 million) aged 18 and over, report some kind of hearing problem. 13% of the United States residents aged 12 or more (some 30 million people) have been diagnosed after standard hearing examinations to be experiencing hearing loss in both ears. More severely, a 2% of adults between 45 and 54 suffer from disabling hearing loss. As age increases, in the slot 55 to 64, this disability affects the 8.5% of the population. For those aged 65 to 74 the percentage rises to 25%, while for the ones who are 75 and older disabling hearing loss affects the 50% of that population group. According to these figures, hearing disorders impact adversely

the patient's quality of life by predominantly disrupting his oral-aural channel of communication (Stavrakas et al., 2016).

While hearing disorders directly affect the voicing mechanism, they have some smaller in extend negative influence on the way that musicians skillfully interact with their instruments in order to produce harmonic tones that bring to prominence beauty of form, harmony and emotion. Indeed, the distracted perception of musical sounds not only represses the ability of the performer to tacitly interact with his musical instrument, but is influencing the behavior of listeners who pervasively dip into oceans of digital music (Margounakis & Politis, 2011) supposedly delighting their ears. Actually, although the way that classically educated musician interact with computers has not changed in its essence the last 20-30 years, the general public has started to interact with computers, mobile devices and the

sound cloud in a two-way manner that enables computer aided synthesis and composition of new sounds, recording and mixing using smartphones and laptops, distribution through on-line libraries and repositories, (live) streaming services, and ubiquitous listening to music on smartphones and other portable music players (Tzanetakis, 2016).

Despite all these sweeping advances that raise the everyday audiophile to an enthusiastic producer, people who are hard of hearing lack the harmonic understanding or have impaired perception of natural tones struggle to participate in these social networks.

Hearing loss can be divided into two main categories, depending on the affected parts of sound transmission:

1. Conductive hearing loss results from any disruption in the passage of sound from the external ear to the oval window. It can be caused by pathologies involving the external and middle ear (external auditory meatus, tympanic membrane, ossicular chain).
2. Sensorineural hearing loss results from disruption of the passage of sound beyond the oval window. Such pathologies can be located to the auditory receptor cells of the cochlea and the eighth cranial nerve.

3. Mixed hearing loss represents a mixture of both conductive and sensorineural hearing loss.

Pure tone audiometry for producing audiograms is performed in an audiometric test room, where the subject's face should be clearly visible to the tester. When the test is observed from outside the audiometric test room the subject should be monitored through a window or a TV monitor. Excessive ambient noise can affect test results, thus it is recommended not to perform the test if the ambient noise is $>35\text{dB}$. Both ears are tested for air conduction firstly at 1000Hz and then at 2000Hz , 4000Hz , 8000Hz , 250Hz and 500Hz . A reference level of 0dB HL conventionally represents normal hearing across the entire frequency spectrum.

Some basic thresholds are the following:

- Threshold of hearing, 0 dB
- Whisper from 1m distance, 30 dB
- Normal conversation, 60 dB
- A shout, 90 dB
- Discomfort, 120 dB

The interpretation of the audiogram provides information not only for the quality of any potential

Figure 4. Left: the hearing process. Right: An Audiogram for normal hearing, in dB of Hearing Level versus frequency. air audiometry (o) and bone conducted audiometry (<) (Stavrakas et al., 2016)

Figure 5. Left: Conductive hearing loss with an obvious air bone gap in its pure tone audiogram. Center: Sensorineural hearing loss audiogram. Right: Mixed hearing loss. All audiograms after Stavrakas et al., 2016.

hearing loss (conductive, sensorineural or mixed) but for the level of hearing loss as well. Generally, normal hearing is considered to be >20 dB, while mild hearing loss is >40 dB. Hearing thresholds and degrees of hearing loss are summarized pictorially in Figure 5 (Stavrakas et al., 2016).

Unlike a hearing aid, CI does not make sound louder or clearer. Instead, the device bypasses damaged parts of the auditory system and directly stimulates the nerve of hearing, allowing individuals who are profoundly hearing impaired to receive sound” (Figure 6).

CIs are applicable for both children and adults with bilateral, severe to profound sensorineural hearing loss, who cannot take advantage of the use of powerful hearing aids and have not managed to improve their oral communication skills by a prescribed speech therapy. In this manner, the early stimulation of the acoustic Central Nervous System, especially in pre-school ages, may well lead to improved acoustic memory and sound discrimination.

Indications and preoperative requirements for cochlear implantation include a complete medical history and physical examination, medical valuation, audiologic examinations, CT and MRI scans to evaluate the cochlea and the auditory nerve, psychological tests, speech evaluation and enrolment in oral education program (Kyriafinis et al., 2007).

CIs do not restore normal hearing; they just provide a *representation* of sound. An inner ear problem, usually leads to sensorineural impairment or nerve deafness. In most situations, the hair cells are damaged and do not function. Even though various auditory nerve fibers may be intact and can transmit electrical impulses to the brain, these nerve fibers are unresponsive due to hair cell damage (American Academy of Otolaryngology, 2015). It is generally accepted that if severe sensorineural hearing loss cannot be put right with medical treatment, then the road towards cochlear implantation is wide open.

Figure 6. Applying a Cochlear Implant to a child at the AHEPA hospital, as seen with a CT head cross-section (left), and as it seen from outside (right), with an obvious attempt to camouflage the external parts of the implant.

FURTHER RESEARCH DIRECTIONS: ESTABLISHING A BCI MODEL FOR ORAL AND AURAL COMMUNICATION

It is obvious that cochlear implantation, along with highly immersive and invasive audiovisual and kinetic devices deploy a BCI that more or less revamps the Human Processor Model (Card et al., 1986) that was first established in mid 1980's by adding a blend of virtual reality sensing.

Indeed, the situation depicted in Figure 6 can be diagrammatically explained with the computer architecture module seen in figure 7.

The initial model proposed by Card, Moran and Newell, provided a workable simulation for analysing how human cognition responds in a HCI manner with the plethora of incoming signals that test the ability to see, hear, or become aware of something through the senses.

However, prosthetics and implanted devices offer a potential that did not exist in the original 1986 model, which could not envisage the possibility of desirable future characteristics (Pesaran et al., 2006), like an “audio processor” or a “graphics processor” apart from the Central Processing Unit.

This new approach propels theories that take into account special capacities that enable indi-

Figure 7. The diagram for the revamped Human Processor Model (cropped from <https://blombladivinden.wordpress.com>)

visuals to display exaggerated performances and skills, which cannot be explained in depth by the theories of intellectual performance based on a person's reasoning ability.

Prosthetics, bionics and augmentation devices allow subjects to readily experience an augmented virtual reality that gives them, although handicapped and impaired in normal physiological values, the possibility to experience the production of sensual impressions stimulated by "parts" of their body, or provoked by other senses.

For instance, a patient with a CI does not use the middle and the external part of his ear at all; instead, he is able to hear through an audio processor that establishes a sensorineural channel of communication between a computer device, the speech processor, its bionic extension, which is implanted within the skull, and a BCI, the place where the electrodes are conclusively settling and clinching the hair cells of the audio nerve (Figures 3 and 6).

Indeed, all this arrangement is well described by the auditory processing channel seen in Figure 7. Furthermore, it may give the impression that the sense of hearing is completely replaced by a bionic part, and therefore the normal hearing ap-

paratus is not contributing to the bodily function of hearing.

Therefore, if the CI's battery is uncharged, or if the subject turns off the CI, then, he may not receive or process any auditory input. However, this is not the case. If, for instance, the subject is in a music hall and he is listening to dance music, which is highly rhythmic with strong subwoofer beats, he will not be able to hear the melody, but the strong beats via the ear's auditory canal will trigger with their vibrations the vestibulocochlear nerve, attesting the sense of balance. For a deaf subject, no sound or melody will be heard, since the bionic device is turned off, but, the strong vibrations will be sensed by the vestibule, sacule, superior canal and posterior canal, and therefore the subject will have a clear sense of the rhythm, allowing him to dance in accordance (Figure 8).

This ability, to have multiple representations of sounds, is stimulating the virtualization of our senses, by intermingling perceptual processors (which can be our senses or bionic devices) with the cognitive processor, which is our cerebral processing power, responsible for the integration of complex sensory and neural functions and the initiation and coordination of voluntary activity in the body.

Figure 8. Left, the hearing mechanism triggered in the outer and middle ear. Right, the structures that are triggered within the inner ear.

This approach can be somehow adequately incorporated with the theory of Multiple Intelligences (MIs).

The profiles of intelligences and their basic description defined by the MI theory are (Aleksic & Ivanovic, 2016):

- **Verbal/Linguistic:** Represents the primary means of communication amongst humans. It is reflected in symbolic thinking, language, reading, and writing.
- **Logical/Mathematical:** Is used for data processing, pattern recognition, working with numbers, geometric shapes.
- **Visual/Spatial:** Navigation, map making, visual arts, architecture, perspective.
- **Bodily/Kinesthetic:** Reflects the precise self-body motion control, non-verbal emotion expression, dance, fine hand-eye coordination.
- **Musical/Rhythmic:** Recognition and use of rhythmic and tonal patterns, recognition

of sound, speech and music instruments. It is used to interpret and create music.

- **Natural:** Recognizing patterns in nature, classification of objects and types of wildlife
- **Interpersonal:** The possibility of cooperation in small groups, communication with other people, individual's ability to recognize other people's intentions, mood, motivation, non-verbal signs.
- **Intrapersonal:** Recognizing own abilities, capacities, feelings, emotional reactions, self-reflection, and intuition.

Evidence of existence of a theoretical ninth (existential) intelligence has not been clearly established (Moran et al., 2006), so it will not be considered.

The theory of MIs has spread waves of enthusiasm in various educational circles since it promotes both an individualized approach and practical application in teaching. Researchers thus

recognize that by supporting multiple areas of activity they may enhance the students' mindset and better exploit it, especially amplifying its verbal and linguistic aptitude. MI theory increases learning efficiency by expediting instructors to direct further assistive education (Stagiopoulos et al., 2016).

Furthermore, it can be said that as sound or music experience is a complex procedure that involves multiple human sensors intermingling with virtual instruments or virtual worlds (Tzanetakis, 2016), that a more complex scheme should be used to represent logically, mentally and mathematically the multitude of HCI and BCI events.

Several systems have been proposed in various occasions, e.g. like that of Valbom & Macros (2003), Miranda & Wanderley (2006), Graham-Knight & Tzanetakis (2015), Politis et al. (2015)

that give an idea of the multitude of interaction with the world of music. New devices, new instrumentation and ample computer resources reshape the way that people either alone or en masse participate to the increasingly global music recreation (Figure 9).

CONCLUSION

Playing a musical instrument, speaking properly a (foreign) language or being able to sing with the right tune are undoubtedly some of the most complex interactions for the convolution of oral and aural communication. All people have a lengthy experience of schooling for becoming able to handle properly their speech, language and musical communication skills. Furthermore,

Figure 9. Interacting with musical instruments. Left, a performer playing his guitar. Center, a virtual guitar with multitouch capabilities that can be played with an iPad. Right: A new concept for multisensor music reproduction – a “virtual” compact disc surface enabling the DJ to perform cueing effects with his hand.

Figure 10. The axes for developing augmented communication skills between prostheses, implants and wearable devices

the ability to manipulate the multiple aspects of linguistic ability (phonation, formation of speech, structural organization, etc) characterizes the overall competence of a subject's potential for his perceived general intelligence, at least for the schooling age.

A new perspective in the management of these capacities comes with the advent of devices that offer a bionic support and augmentation in proliferating oral and aural channels of communication.

Having already presented outstanding features in supporting communication with peers, they have commenced to demonstrate impressive features in their communication with the Internet, with digital technology equipment, with devices that make sound using music robotics and ultimately with wearable devices, portable devices or prosthetics that create an everyday virtual reality experience beyond expectation.

In any case, to manage the great expectations that have been created as far as handling, programming and interaction are involved, the three pivotal points exposed in Figure 10 should be adequately balanced.

KEY TERMS AND DEFINITIONS

BCI: The Brain Computer Interface research and development engulfs all the neuroprosthetics applications that focus in repairing, augmenting, and assisting human cognition or sensory-motor functions.

CT: Computed Tomography scans are special X-Ray tests that after being processed by computing machinery reconstruct detailed images of inner body structures and organs.

EEG: ElectroEncephaloGraphy is a monitoring methodology that gives concise measurements of the electrical activity of the brain while it performs cognitive tasks. Some 20 electrodes or more can be positioned on the skull to monitor small electric signals produced by brain functions. **GUI:** By the term Graphical User Interface is denoted the integral part of computing machinery that relies on graphic representations to carry out

commands. It also depicts visually the results of computer interaction establishing multimodal graphic communication between the smart device and the end user.

HCI: Human Computer Interaction is the scientific field that observes in depth how humans use all kinds of computing machinery, aiming to exploit the efficiency and effectiveness of their control potential by designing in cognitive and applicative terms new services.

MRI: Magnetic Resonance Imaging uses magnetic fields and radio waves to produce detailed images of the inner body. MRI may reveal problems that cannot be easily diagnosed by X-rays, ultrasounds or CT scans.

Senses: While computer research has put as goal to replicate the five senses, it becomes evident that machine perception can simulate, especially in gaming, some other sensations too, like vertigo, balance, equilibrium, acceleration, dizziness, magnetoception and so on.

UI: User Interface is the imminently responsive part of computable processes and structures. By it users can interact with a smart device.

VR: The synoptic term Virtual Reality refers to all the computer generated environments that create artificial worlds to feed our senses. Various devices like gloves, headsets, headphones, joysticks, eye cameras, 3D glasses, gamepads, motion controllers and similar offer to users simulated environments to “inhabit” and “wander in”.

Personalized Medicine

Sandip Bisui

Indian Institute of Technology (IIT) Kanpur, India

Subhas Chandra Misra

Indian Institute of Technology (IIT) Kanpur, India

INTRODUCTION

Electronic Medical Record (EMR) and Personalized Medicine (PM) systems utilize new strategies for genomic diagnosis to better deal with a patient's ailment or inclination towards a sickness. PM intends to accomplish ideal restorative results by helping physicians and patients pick the disease management approaches prone to work best in the setting of the patient's genomic profile and genetic data. Such methodologies might incorporate genetic screening programs that all the more precisely analyse sicknesses and their types offering physicians the right assistance with selecting the right treatment and most appropriate drugs best suited to that genomic group of people (PMC, 2010, PMC, 2014). EMR and PM systems consist of identifying nature and contribution of genes as well as different environmental factors and preparation of personalized drugs based upon the information derived. PM system can then facilitate disease prediction, prediction and treatment by determining whether an individual runs the risk of developing a disease. Thus PM system can develop early prevention strategies. It can dragonize disease faster. Therefore, treatment can be started early. Thereby, it is possible to prevent side effects that resulted from medicines given to a patient by trial and error method using the traditional system of treatment. Thus the main merits of PM system can be summarized as follows (PMC, 2007):

1. In this novel system, it is possible for the medical practitioners to prevent onset of different diseases more effectively.

2. It is more time and cost effective.
3. This treatment procedure bears the potential to reduce the possibility of adverse reaction of drugs.

However, it is to be borne in mind that for successful adoption of EMR and PM systems it is very important to first identify the critical challenges (Misra and Bisui, 2014), changes required (Misra et al., 2016), and trust, privacy and security concerns in the adoption. This act of identification will significantly add to the success of the personalized healthcare system management. As indicated above, the novelty of EMR and personalized healthcare lies in the fact that it makes use of information regarding environment, genes, proteins and clinical treatment of individual patients.

BACKGROUND AND MAIN FOCUS OF THE ARTICLE

Personalized Medicine is a recently developing idea in the modern health sector. Some of the personalized drugs have been now found by the researchers. However, reception of the Personalized Medicine and EMR idea still lacks practice implementations. Despite the fact that there are a several researches about on the genomic translation and genetic interpretation by Esvelt and Wang (2012), Dreyfuss (2012), Zamft et al. (2012), Cong et al. (2013) and Mali et al. (2013) advancement of exploration on various parts of Personalized Medicine is very insufficient. Bolouri (2010) has talked about a few issues

DOI: 10.4018/978-1-5225-2255-3.ch513

regarding personalized medicinal services. Eysenbach (2001) and Ahern et al. (2006) gave some insights about electronic healthcare. In a survey Jadad et al. (2005) and Eysenbach and Diepgen (2001) gave some direction towards the electronic medicinal services framework. There is an active promotion of e-health across the world. Several developed countries including Canada, United Kingdom and United States have a long-term plan to implement EMR. Taiwan has already adopted EMR and EMR Exchange. Canada had the goal to have EMR for all its citizens by the time of 2015. United Kingdom is building integrated IT infrastructure and systems to transmit health information safely and efficiently. United States has invested billions to encourage physicians and hospitals to adopt EMR and other applications of healthcare Information technology (HIT). Thus, the active promotion of EMR and EMR exchange is one of the important goals of health policy across the world (MRI, 2004). However, when it comes to developing countries, the success rate of the EMR adoption is not very high. Although Taiwan has implemented it, but physicians and clinics are still in a dilemma when it comes to practice implications of EMR and EMR exchange (Hwang et al., 2012, Chang et al., 2009, Chen et al., 2010). Countries like India, Netherlands and Australia are still trying to implement EMR and E-Health system. There are several challenges, trust issues, privacy and security concerns in this new technology adoption. We will try to discuss these issues further in this article.

SOLUTIONS AND RECOMMENDATIONS

While older people are more prone to drug adverse reactions because they are more likely to have multiple ailments and treatment of all the health problems need to be addressed simultaneously. Among younger generation people too, treatment by using personalized medicine is becoming increasingly attractive after the detec-

tion of the effect of the genetic background on the disease susceptibility and response to treatments. Pharmaceutical industries also indicate that the introduction of Personalized Medicine will ease the healthcare management to a significant extent. Personalized drugs are getting popular day by day. Personalized Medicine drugs will allow companies to provide a wider variety of drugs, each targeted to a smaller and more specific category of patients. In this way, adverse reaction of traditional drugs in patients' body can be minimised. Researchers have identified some issues regarding the implementation of Personalized Medicine. For any new technical adoption several managerial needs to be accessed before practice adoption. For this new healthcare paradigm we need to identify the feasibility of the adoption in the current scenario. The critical challenges those may hinder the adoption also needs to be known. The changes are required to the current practice must be identified. Success factors of the new medicare system will give the healthcare institutions an insight about what needs to be done for a successful adoption. Several trust issues may be associated with the consumer, privacy and security of the genomic database will also be an important concern. Therefore, one need to have an insight about all these issues before actually goes for a practice adoption. In this article we have tried to portray some key aspects regarding the above issues. A brief discussion has been made on the previous researches. A direction for future researches has also been given in this article.

Feasibility of the Personalized Medicine System in the Present Scenario

There are various reasons to think whether Personalized Medicine is really needed. Often many medical practitioners and patients feel that it is just a marketing hype (Bolouri 2010). However, it is to be kept in mind that the world population is growing rapidly and older people require better healthcare support. Importantly, older people have

varied health history, and therefore, have much diversified healthcare needs. They are also more prone to drug adverse reactions because they are more likely to have multiple ailments and treatment of all the health problems need to be addressed simultaneously. Among younger generation people too, treatment by using personalized medicine is becoming increasingly attractive after the detection of the effect of the genetic background on the disease susceptibility and response to treatments. Thus personalized medicine is needed by a large proportion of people.

Challenges Involved in the Adoption of Personalized Medicine

Misra and Bisui (2014) recently explored the challenges for the adoption of Personalized Medicine system within the healthcare management. The authors conjointly argue systematic and elaborate discussion on many vital aspects of personalized health care system. Within the same academic article, the authors have dwelt on variety of problems that provide hindrance to the implementation of this electronic healthcare system. The author analysed the crucial challenges from the perspective of medical physicians and common people. They have mentioned that there is a significant difference in both prospects. Some challenges include,

Genomic analysis for all individuals, High initial cost with no clear Return on Investment (ROI), Current healthcare work place doesn't have the training to administer Personalized Medicine, Present structure of medical record system doesn't have the infrastructure for Implementing Personalized Medicine, Unavailability of personalized medicine, Personalized Medicine concepts and tools have not yet been incorporated in medical school criteria, Government agreeing for the payment of the genomic tests, Complex cases where Personalized Drugs haven't yet discovered, Unawareness of doctors about personalized medicine, Ever increasing cost of health care, Insurance companies agreeing for the payment of the ge-

nomics tests, Categorization of different genomic groups. However, common people also identified Categorization of different genomic groups and Complex cases where Personalized Drugs have not yet discovered as significant challenges in the adoption of Personalized Medicine.

Changes Required While Adopting Personalized Medicine

Several scholars have showed that there are several challenges that need to be taken care of before adopting Personalized Medicine system. Misra et al. (2016) gave us a glimpse of the changes required for this new medicare system to adopt. Their study showed that changes from reactive to efficient medical care, from trial and error to right treatment for right person at right time, from narrow mind-set to open mindedness, from open information of patients to secure information, from less emphasis on IT infrastructure to more emphasis on IT infrastructure are some of the significant changes that are necessary for implementing the revolutionary medicare system of personalized Medicine. Their research gave us more useful and more accurate information necessary for implementing Personalized Medicine systems in the future. The results from their study serve as first step in the direction.

Factors Leading to Successful Adoption of Personalized Medicine

For any technical adoption identifying the critical success factors is a key step. Once the organizations are aware about the factors that could lead to successful adoption, the manager could prepare a plan or pathway to overcome the success factors. Misra and Bisui (2014) while identifying the critical challenges gave a hint of the factors that may have an impact in the success of the Personalized Medicine system. A study in the similar area indicated that data management, team work and composition, privacy and confidentiality, mind-set, return on investment, sufficient time, R&D

and alignment could be possible success factors. However, there is not any academic paper in which an attempt has been made to suggest the critical factors for the implementation of Personalized Medicine in healthcare management. Researchers could identify a multiple regression model for the consolidated dependent variable success, with the dependencies success factors as regressor.

Consumer Trust, Database Privacy and System Security in Personalized Medicine System

While receiving any new innovation the customer trust is dependably a noteworthy concern. In Personalized Medicine framework keeping up the protection and defending the security concerns will likewise assume a noteworthy part in the achievement of the adoption. As there will be a genomic database containing the patients' medicinal and individual data, therefore, keeping up the trust of the consumers will be a noteworthy test. There will likewise be numerous security concerns in regards to the information protection and utilization. Consumers and healthcare provider professionals would likewise be worried about their protection while utilizing this framework. Along these lines, there may be several trust issues could hinder or delay the success in the adoption. Before effectively receive this new medicare framework one needs to address all the trust issues that might influence the accomplishment of this progressive and novel medicare framework. Researchers are trying to identify the issues that may regulate the trust of consumers, however, as per our knowledge there are no academic literature available in this domain. We have taken this issue up and trying to identifying the moderating effect of trust concerns in the success factors of Personalized Medicine. As trust issues are mostly related to people and organization (Robert and Seibold, 2003). Therefore we took the success factors that are directly or indirectly related to people and organization. A brief of our study on the identification of trust issues and their moderating effect on people

related success factors is given bellow. Factors related to consumer and hospital system authorities are identified. These factors are the important modifiers of success. Next trust concerns of the consumers are listed. Finally the moderating effect has been checked using statistical methods. Along with trust privacy is also a major concern in this novel technology adoption. In Personalized Medicine system there will be a genomic database available in the web. This database is going to be the core of the adoption and it will contain all the genomic and personal information of the patients. Therefore, who are accessing the database will be a major concern for the patient' community. The privacy of the consumers will be directly in the hand of the database user. Therefore, common people will be very concern about their privacy. To prevent the privacy breach there will be a strong need of proper technology. Any technical glitch may leak the privacy of the consumer. Therefore, before adopting the Personalized Medicine system there is a strong need of research in the privacy concerns and their moderating effect on the success of Personalized Medicine. Similar to trust issues and privacy concerns, security will also be an important concern to taken care of. The implementation of Personalized Medicine system and E-healthcare platform is going to be very costly. Therefore, there will be high chance of security breach. Healthcare institutions and government should focus on developing policies and regulations to prevent the security breach. A proper research is needed before the practice implementation of Personalized Medicine.

FUTURE RESEARCH DIRECTIONS

Personalized Medicine system is surely to be an important enabler of the E-health system. It could shift the whole e-healthcare platform to a new level, where healthcare cost will be less, treatment time will be minimized and there will be no error in the treatment (PMC, 2007). However, Personalized Medicine system still lags research. There is not

much academic study in the implementation of this novel technology. Misra and Bisui (2014, 2016) and Misra et al. (2016) have provided some business models for the critical challenges, feasibility and changes of this system. However, more work needs to be done in the area of trust, privacy, security concerns of the novel technology. Shalhoub (2006), Hwang et al. (2012) have identified different trust, privacy and security concerns for the EMR adoption. Although there are some research works available in the area of EMR adoption and E-health implementation, however, current academic still lags works in Personalized Medicine implementation. We have given a glimpse about the possible research works that can be done in this area. Personalized Medicine system surely is an important asset/discovery for our society. Therefore, researchers must have to be focused in its implementation. Several countries including United States, Canada, Australia, India, Taiwan have taken the implementation of EMR and Personalized Medicine system seriously. Therefore, these research works could be very helpful to the administrators and healthcare care providers while adopting this new medicare technology.

CONCLUSION

The research works in the area of adoption of Personalized Medicine serve as a vital step towards an essential comprehension of the rising field of Personalized Medicare framework. The conceivable purpose behind these research works is to minimize the current healthcare cost and provide our society a better and efficient healthcare system. Personalized Medicine will be a vital enabler in this. Adoption of EMR and electronic healthcare system has broadened the pathway for Personalized Medicine. Several authors and organizations Misra and Bisui (2014, 2016), Misra et al. (2016) Hwang et al. (2012), NHMRC (2011), Ginsburg and McCarthy (2001), Ong et al. (2013), PMC (2007, 2010, 2014) have started working in the practical implications of the Personalized Medi-

cine. The outcome of the research works could serve as a noteworthy step towards the adoption of Personalized Medicine. We may hope that soon there will be an era of Personalized Medicine in the healthcare sector. Physicians, healthcare administrations and government could use these results to make new policy and regulations for the successful adoption of Personalized Medicine.

Pervasive Mobile Health

Muhammad Anshari

Universiti Brunei Darussalam, Brunei

Mohammad Nabil Almunawar

Universiti Brunei Darussalam, Brunei

INTRODUCTION

Recent progress in mobile health (mHealth) is very encouraging as it allows healthcare services to be accessed through powerful smart mobile devices. Nowadays smart mobile devices such as smartphones and tablets support many features that can be utilized to access healthcare services conveniently. mHealth will indeed be a convenient experience to patients since there is currently a growing trend towards pervasive knowledge acquisition and management. Pervasive mHealth is an electronic health where healthcare services can be accessed regardless of time and place, and patients can continuously be connected to their healthcare services through their smart mobile devices.

According to Eysenbach (2011), healthcare services in mHealth are delivered through mobile devices. Pervasive mHealth provides services that go beyond traditional healthcare services. It provides various services accessible through smart mobile devices, including searching relevant health information, interactive discussion of healthcare matters with colleagues or friends, updating health related information from smart mobile devices, and seeking opinion through online healthcare services. Pervasive mHealth is becoming an increasingly important instrument in healthcare services for the public.

Most healthcare initiatives perceive patients as recipients of healthcare, where they hardly have roles in the process of healthcare activities and decision-making. For example, it is difficult for a patient to get access to his/her own health

record or to find out his/her health history. On the other hand, the advancement of mobile technology has given customer (patients) a greater role in the process including the ability to gain access and control of information flow that fits their personalized needs. In terms of healthcare activities, many smart electronic devices have enabled patients to check their own health condition without assistance from healthcare staffs such as checking blood pressure, food hygiene Apps, mobile thermometer, mobile glucose measurement, mobile hypertension tool, etc.

In addition, the wide adoption of smartphones and tablets as well as the emerging of their utilization in healthcare raises the possibility to engage patients, patients' families, and society to participate in their own healthcare processes. For instance, social networking, which is accessible through smartphones, can provide an avenue to identify any misuse or misunderstanding in consuming antibiotics, share health information, promote positive behavior change, disseminate valid information, and explore how such tools can be used to gather real-time health data (Scanfeld et al., 2010). Pervasive mHealth can offer healthcare providers a comprehensive perspective of patient's condition and thus provide an environment in achieving complex healthcare goal(s) such as building lasting relationships with patients. The main goal of this chapter is to accommodate the concept of pervasive mHealth scenario within pervasive knowledge acquisition in healthcare systems. We propose a pervasive mHealth model that extends to multi-channel knowledge resources in mHealth. The model is designed to establish

longitudinal healthcare services anytime and anywhere which in turn will raise health literacy of individuals and the community at large.

BACKGROUND

Currently almost every healthcare organization depends on information and communication technology (ICT) in every level of their activities. One of the most valued aspects of ICT is its capability to enhance processes or functions to improve consistency, accuracy, and efficiency. Similarly, efficient and effective healthcare services have become increasingly dependent on accurate and detailed clinical information, which is transferred from interrelated departments or even between organizations (Conrick, 2006). In addition, people's demands have changed because they have been empowered by the vast amount of information available and accessible to them through smart mobile devices, including mHealth related services (Anshari et al., 2013). For example, half of smartphone owners in US use their devices to get health information and one fifth of smartphone owners have health-related apps (Fox & Duggan, 2012). Despite some limitations of smartphones (Koushanfar et al., 2000), they can be used as services platform for mobile health information delivery, access and communication (Nkosi et al., 2010).

Rapid adoption of smartphones and smart mobile devices has removed the space, time and distance barriers for users, including the patients, to access information. In fact, smartphones facilitate the use of dynamic Web 2.0 and Apps allows intensive and immediate interactivity through social networks. In Web 2.0, users can collectively contribute contents and applications (O'Reilly, 2005). Web 2.0 is defined as a set of economic, social, and technology trend that collectively forms the basis for the next generation of Internet – a distinctive medium characterized by users' participation in using networks such as *Facebook*, *Twitter*, *Snapchat*, *Instagram* and *LinkedIn*, which have

indeed grown rapidly, facilitating peer-to-peer collaborations, participation and networking. The term social networks refer to the use of Web 2.0 that describes the social characteristics supporting the promotion of collaborative sharing. Web 2.0 is commonly associated with technologies such as weblogs (blogs), social bookmarking, wikis, podcasts, Really Simple Syndication (RSS) feeds (and other forms of many-to-many publishing), social software, and Web application programming interfaces (APIs) (Kristaly et al., 2008). Web-oriented applications and services use the Internet as a platform to provide unique features by engaging and providing users with rich interactive experiences (Rodrigues & Vaidya, 2010).

The widespread acceptance of the Web 2.0 services will affect the operation of future businesses. Greenberg (2009) explained these changes and that the customer's ownership of the conversation ultimately leads to organizations readjusting their business strategy. The fast adoption of smartphones has made customers or patients demand accessibility of health services through their smartphones. It is imperative for Health service providers to respond to these demands to sustain their businesses. In fact, health service providers can provide services that take advantage of smartphones' features or other mobile devices such as Web 2.0 features. The use of smart mobile devices with the Internet connection has permeated almost all aspects of our lives, creating pervasive computing.

Pervasive computing is associated with smart environments in which information and communication technologies employ intelligence and machine learning techniques to reason about, control and adapt to our physical surroundings. It focuses on sensing, interacting with and aiding humans at an individual and community level (Cook & Das, 2004). This means that pervasive computing should encompass every device worldwide that has built-in active and passive intelligence (Saha & Mukherjee, 2003). While mobile computing supports IT such as remote information access and adaptive applications, pervasive computing

extends this notion to provide computing and communication capabilities that are integrated with users (Weiser, 1991).

MOBILE HEALTH

Challenges and Opportunities

As a business entity, a healthcare provider needs to have a comparable standard of customer service with other business organizations. It is a fact that customer expectations in healthcare are high, creating serious challenges for healthcare providers as they have to make an exceptional impression on every customer. In a competitive market, poor service drives customers to switch from one healthcare provider to another (Anshari & Almunawar, 2011). The adoption of mHealth will be a natural consequence of the adoption of smartphones. Hence, healthcare services must be adjusted in such a way that people can access the service through their smartphones or other mobile devices.

Most recent healthcare initiatives perceive customers (patients) as recipients of health care as they do not have a significant role in the decision-making process of their health (Anshari & Almunawar, 2015a). However, the advancement of Web 2.0 offers patients to have a greater role in the decision-making process related to their health. This is because they can be provided with the ability to access and control some personal information that fits with their personalized needs, which allows them to actively participate in the decision-making process related to their health.

Web 2.0 tools have brought a possibility to extend e-health by enabling patients, patients' families, and the community at large to participate more actively in the process of health promotion and education through a social networking process (Almunawar, Anshari, & Younis, 2015). Embedding Web 2.0 in healthcare is a challenging task in order to provide a new meaning in building relationships between patients and healthcare

organizations within a social network platform. In addition, social network applications that exist in smartphones can be utilized to facilitate interactions between patients and their healthcare providers (Anshari & Almunawar, 2015b). Furthermore, the impact of Web 2.0 technologies for health continues to grow, and the term Medicine 2.0 has entered popular categorization. Hughes et al., (2008) mentioned that the terms of Medicine 2.0 and Health 2.0 were found to be similar and categorized into five major notable cores:

1. The participants involved (doctors, patients, etc.);
2. Its impact on both traditional and collaborative practices in medicine;
3. Its ability to provide personalized health care;
4. Its ability to promote on going medical education; and
5. Its associated methods and tool related issues, such as potential inaccuracy in end user-generated content.

However, discussion on Medicine 2.0 needs further investigation to map the relationship model of patient-patient interactions, and patient-healthcare provider interactions. This chapter proposes that the role of patients in mHealth services can be extended into an individual health actor, a social health agent through social networks, and a medical care partner.

Managing interactions in any business organization requires proper concepts, business process, tools, people, and strategies. Therefore, mHealth model must provide a mechanism that have the ability to broaden service beyond its usual practices. Three aspects of interaction in mHealth can be considered (Figure 1). First, *patient-self interactions* with the system, which is the ability of a patient as an individual to actively utilize mobile healthcare services provided by the healthcare provider. For instance, patient-self interaction enables the patient to view his/her medical records through his/her mobile phone,

or request for a consultation. Secondly, *patient-to-patient interactions*. This allows patients to interact among themselves, share information, concerns, and experiences. For example, the system facilitates social networks for patients with similar conditions to make conversation and share their experiences. Thirdly, *patient-to-staff interactions* provide online interaction between patient and healthcare staff.

Finally, the development of the Internet of Things (IoT), big data, and massive medical software applications (apps) has supported the generation of pervasive knowledge including mobile health devices. Mobile health devices have empowered patients to use care tools such as drug references, healthcare references, diagnostic aids, medical calculators, etc. Whenever mobile health devices connects with mHealth system it can generate information that enriches personal health records. For instance, a blood pressure tool measures a patient's blood pressure and instantly updates the record of his/her blood pressure in the mHealth system. The focus of pervasive mHealth is recognized in different areas of data and information management, including accessibility, collaboration, information utilization, integration, and process automation of mHealth data.

Figure 1. Interactions scenario in mHealth

Solutions and Recommendations

Active role of patients through mobile services is delineated as the embodiment of future mHealth, with the hope to make the system more reliable, effective and efficient in addressing patients' demands. The model addresses multi levels interactions to provide online information access, consultations, information sharing, and other services through smart mobile devices. The model is expected to lay the perspective for pervasive knowledge management in which mHealth provides service for improving healthcare literacy and building relationships among all the parties involved (a healthcare organization, patients, and the community at large).

Understanding a business process helps healthcare organizations to deliver the strategic plan in providing proper mHealth services. The model combines social networks, mobile health devices, and knowledge health database (Figure 2). It is important to examine each business process as a layer of value to the patients. Patients place a value on these services according to the quality of outcome, service, and price. The value of each layer depends on how well they are performing. If the processes do not correspond to the strategy, the value will be significantly diminished. For example, the value of mHealth is reduced by any delayed responses to patients' queries or healthcare staffs' poor communication skills.

Figure 2 depicts the model of pervasive mHealth with features of social networks, pervasive knowledge management, and mobile health devices. Mobile health devices support personalized healthcare anywhere and anytime in delivering healthcare service to users. Social network has enabled patients to dynamically enrich their personalized information. Conventional systems have relied solely on static information provided by the service provider. However, they are now empowered with the ability to conduct conversations with other patients to share and exchange experiences through discussions in social networks.

Figure 2. Proposed model of pervasive mHealth

Pervasive mHealth offers patients a greater role in active healthcare processes by empowering them with the ability to control and generate flow of information that fits with their personalized needs. Pervasive knowledge in mHealth is proposed to enhance all actors in the system (patients, healthcare staffs, automate smart mobile devices, etc.) to generate content with relevant knowledge from various channels. The concept of pervasive knowledge in the model is to enable multi-channel knowledge that is available in the Internet. Knowledge health database can link information across different online sources to form a more comprehensive knowledge to support synchronous lecture, asynchronous study, online consultation, knowledge sharing in social networks.

In addition, the model accommodates the three dimensions of mHealth: *mPersonal*, *mSocial*, and *mMedical*. *mPersonal* refers to patient-self interaction. *mPersonal* derives functions of personal health activities that cover all personal health related activities in mHealth services as

an individual (patient) which can directly or indirectly affect their health conditions. Activities in this category may include personal Identity (ID), personal Habits of patient (HB), Exercise activities (EX), Spiritual and Emotional activities (SE), personal Health Plan (HP), personal Account information (AC), and so on. For instance, ID consists of personal information in the mHealth system such as name, address, phone no, email address, login ID, and password, where the information solely belongs to personal and a patient (patient-self) is in control of the data. HB stands for daily habits of the individual which may consist of eating, sleeping, and any other habits that can affect personal health. The EX is routine exercise activities of the individual that may be beneficial when they are recorded in the system. *mPersonal* will replace the conventional approach; instead of the health staffs entering personal information into the system, the customers themselves will do it on their own, empowering them.

Secondly, *mSocial* refers to managing patient to patient interactions through social networks.

The social networks refer to the social networks applications such as Facebook, Twitter, LinkedIn, and Instagram, or social networks that are operated, managed and maintained within the healthcare's infrastructure which patients may belong to. This is targeted towards patients/families within the same interest or health problem/ illness to converse between each other. For example, patients with diabetes will be motivated to share his/her experiences, learning, and knowledge with other diabetic patients. Constructive conversation and information from external or internal social networks should be captured as it is an excellent, innovative strategy to improve services. mSocial enable individuals and the community as social health agents for others in mHealth systems. mSocial accommodates the concept of social network within mHealth services. Some activities in this category include conversations (CS), chatting, updating status, forums, wikis, blog, knowledge management (KM), group knowledge and asking for specific services (RS). Nowadays, people constantly use social networks in their daily lives. Updating status in social networks trigger conversation among circles of friends. Bringing this scenario into mHealth services is both interesting and challenging. For instance, patients with the same condition like diabetes may share their experiences with other patients in social networks. Sharing in social networks may become a virtual supporting group that can enrich and strengthen their motivation to fight for better health. In fact, social networks also affect the relationship between the healthcare provider and customers (patients). Therefore, embedding mSocial in mHealth is imperative.

Finally, mMedical refers to the interactions between healthcare/medical staffs with patients. In fact, mMedical is the core activity of mHealth, because it is where patients raise medical concerns through mobile devices and are responded by dedicated medical staffs managing mHealth services. mMedical proposes that patients can be involved in the medical care processes and medical decision-making in the mHealth scenario. Any medical

queries from patients can be facilitated through the module available in mMedical. mMedical's module may consist of examination (XM), mAppointment (MA), mPrescription (MP), and mTreatment (MT). XM is online consultation between patients and medical staffs which can lead to the generation of electronic medical record (EMRs) for the patients. It is a common service in many e-health initiatives; however, when there is empowerment or participation from patients in these processes of medical activities, the result of consultation can be accessed by patients directly, anytime and anywhere. For instance, many healthcare providers prevent patients from accessing their EMR. In fact, those patients are not in the position to track their medical history themselves; whenever the patient needs consultation, the diagnosis will start from the beginning. mMedical should enable patients to have access over their medical records regarding their health status, condition, and history anywhere-anytime. The MP is another subset of EMR, another area in which customers need to be empowered. Empowerment in MP will speed up the process of managing prescription, and customers will know how to consume their medication appropriately, as they are able to access and learn anytime-anywhere. In summary, participation and empowerment in mMedical can shift the role of a patient from a recipient of care, to a partner of care. Access to knowledge and contents (EMR) will make patients more knowledgeable on their health conditions and issues.

FUTURE RESEARCH DIRECTIONS

The advancement of pervasive mHealth is expected to improve interactions of all actors. Those interactions range from patient-patient, patient-healthcare provider, patient-community, healthcare-community, and smart mobile health-patient. Meanwhile, there are a lot of opportunities for broad arrays of research in developing smart mobile health devices that will integrate all data into a single platform of mHealth. In addition,

empowerment in mHealth will continue to grow in three subdomains; *mPersonal*, *mMedical*, and *mSocial*. *mPersonal* can be the first module to be tested for deployment since the data generated is less complex, involving data on personal health habits. Secondly, *mSocial* encourages patients to share and support other patients with their knowledge and experiences. From an organizational perspective, *mSocial* can be an effective marketing tool to promote services to customers. *mSocial* can also be utilized as a place to capture ideas from customers. Further studies in developing listening tools will help healthcare organizations to better understand their customers' needs. Thirdly, *mMedical* is the core of the mHealth's system because critical data is stored in this module. It is important to decide which data can be shared with patients and which cannot. This issue needs to be carefully studied, including any related legal aspects. Although this study covers a broad-spectrum of issues across multiple domains, the four primary potential target groups for this study are:

1. Customers (patients / patients' family) who need to be informed, empowered, educated, and connected with others to encourage information or knowledge sharing.
2. Healthcare providers that are seeking innovative ways to improve their customer relationship, loyalty, trust, customer satisfaction, market leader, and any state of interactions.
3. Government and policy makers who seek innovative healthcare solutions through mHealth services with less budget for their citizens.
4. The researchers who need to fully understand the concept of healthcare business processes, technology, and the issues of each domain.

CONCLUSION

Pervasive knowledge is generated from various channels and tools. It can come from smart mobile

health devices, social networks, Internet of Things (IoT), and knowledge health database. Integrating all the resources will provide personalized service in pervasive mHealth scenario. Pervasive mHealth extends multi channels sources and interactions from all actors. Those actors are patients, healthcare providers, social networks, mobile health devices, and knowledge health database. Pervasive mHealth covers three domains of patients' empowerment to ensure interactivity and participation in the healthcare processes. Finally, accommodating the advantages of each model above will give the opportunity to improve the mHealth services that are expected to meet users' demand which is the concern of this study.

KEY TERMS AND DEFINITIONS

Electronic Health (e-Health): According to WHO (2005) is a cost effective and secure use of ICT in support of health and health related fields, including healthcare service, health surveillance, health literature and health education, knowledge and research.

Health Information System (HIS): Refers to any system that captures, stores, manages or transmits information related to the health of individuals or the activities of organizations that work within the health sector. This definition incorporates things such as district level routine information systems, disease surveillance systems, and includes laboratory information systems, hospital patient administration systems (PAS) and human resource management information systems (HRMIS).

Healthcare Business process: Refers to a set of activities which activity adds value to the customer. These are registration, patient care, discharge, marketing, and service.

Healthcare: Refers to the diagnosis, treatment, and prevention of disease, illness, injury, and other physical and mental impairments in humans. Practitioners in medicine, optometry, dentistry, nursing, pharmacy, allied health, and other care providers deliver health care. It refers to the work done in providing primary care, secondary care, and tertiary care, as well as in public health.

Mobile Health (mHealth): mHealth is an extension of electronic health (e-health) in which healthcare services can be accessed through smart mobile devices. The scope of mHealth is mobile personal (mPersonal), mobile social (mSocial), and mobile medical (mMedical).

Patient Empowerment: In healthcare is a principle to give patients more power in making

decisions related to their health and to give them required authority to access or produce information related to their health.

Pervasive Computing: Refers to an embedding microprocessor in device (mobile) to connect and communicate in the networks.

Pervasive Knowledge: Refers to a massive knowledge generated from multi sources of information such as social network, smart mobile devices, and structure knowledge management database.

Smartphone: Refers to a mobile phone built on a mobile operating system, with more advanced computing capabilities and connectivity than feature phones.

INTRODUCTION

Barcoding and RFID-Related Technologies in the Services Sector

Barcodes and related identification technologies have been used to control inventory and supply chain management (SCM) for some time, especially in retail and purchasing applications (Aldaihani & Darwish, 2013; Azadeh, Gholizadeh, & Jeihoonian, 2013; Bhamu, Khandelwal, & Sangwan, 2013). Barcoding equipment is fairly inexpensive and easy to use as compared to other AIDC technologies (Smith, 2011; Smith, Smith, & Baker, 2011; Smith & Rupp, 2013; Visich, Li, Khumawala, & Reyes, (2009; Wilson, 1995; Wyld, (2006). However, certain limitations create the need for a new approach to increase efficiency (Drejer & Riis, 2000; Dutta, Lee, & Whang, 2007; Fisher & Monahan, 2008; Fumi, Scarabotti, & Schiraldi, 2013). Barcodes are only accurate if items are continuously scanned in and out as they move along the supply system. An employee must ensure an item is scanned at each stage, or entry and exit point. An example of this would be a delivery driver that scans packages as a truck is loaded and scans the package at the delivery point. If the package is not scanned, the action is not accurately recorded. Barcodes require an employee to physically inspect the item for scanning purposes to ensure inventory accuracy and determine the product's location, while Radio Frequency Identification (RFID) conveniently

tracks products through radio waves, designed to improve operational efficiency.

RFID technologies helped Walmart to control its inventory and track product movements along its supply chain (Tarofdor, Marthandan, Mohan & Tarofdor, 2013). Furthermore, RFID has been used in the identification of stray pets, which is known as chipping and in transportation, in addition to sports. Experimentation with RFID in soccer may soon allow a visually impaired player to participate in the game by integration of computers and video cameras, along with an active RFID tag to signal to the player through a set of audio headphones (Zare, McMullen & McCune, 2014).

DISCUSSION

RFID in the Healthcare Industry

Anand and Wambaa (2013) performed a case study to evaluate how RFID can be applied in healthcare settings. The authors suggested that there are significant benefits for both patients and healthcare organizations in the application of such technology. Adoption in the healthcare industry is not widely spread because of the initial high cost associated with equipment and technology implementation. One argument against the investment emphasizes that the technology primarily focuses on tracking and implies that the costs outweigh the benefits (i.e., compared to the cheaper alternative of barcodes). However, Anand

et al. compared the evidence collected from 39 hospitals and analyzed the costs and benefits of RFID implementation over the long run. Their findings indicated that RFID-embedded systems can save time and reduce waste.

Hence, RFID-related technologies can help reduce costs associated with the medical supply chain (e.g., pharmaceuticals and medical supplies) or in patient tracking and management. For example, high-valued supplies, such as blood can be equipped with RFID tags that can ensure that the right type of blood is being administered to the right patient (Winters, 2010). When associated with patient tracking, RFID can be used to track patient history as well as hospital admittance, transfer, and discharge. Advantages also include reducing redundant work and time consuming processes by making certain that the correct blood is drawn from storage. This allows healthcare providers to concentrate on patient care and service (Dominic, Goh, Wong, & Chen, 2010; Tarofdor, et al., 2013). RFID-related technologies can also reduce errors and waste by assuring that the accurate drug or medical product, ordered from the appropriate supplier is used at the proper time for the correct patient in the suitable dose.

RFID is an acceptable way to automate and improve the tracking of medical products and pharmaceuticals. Patients gain from RFID-related technology because of the reduction in errors when healthcare providers are prescribing or fitting medical products to them. As suggested by a number of researchers (Smith, 2012, 2013a, 2013b, 2013c; Ting, Kwok, Tsang, & Lee, 2009; van der Togt, Jan van Lieshout, Hensbroek, Beinat, Binnekade, & Bakker, 2008; Wickboldt & Piramuthu; Zang, & Fan, 2007), the experimentation of RFID in a variety of fields [i.e., sports, SCM, operations management, lean manufacturing] may lead to new discoveries and other applications (Hu, Wang, Fetch, & Bidanda, 2008; Ifinedo & Nahar, 2009; Jain, Benyoucef, & Deshmukh, 2008; Johansson & Sudzina, 2008; Jones, Riley, Franca, & Reigle, 2007; Ketikidis, Hayes, Lazuras, Gunasekaran, & Koh, 2013; Koong & Lin, (2007).

The application of RFID technology on the soccer field, for example, may also be applied to patients in the emergency room setting or soldiers on the battlefield; the range of active RFID tag can easily reach 300ft. and can detect direction and motion (Zare, et al., 2014). Emergency room specialists can analyze the information from RFID to track patient movements.

Implications for Medical Supply Chain Management

RFID utilizes radio waves to communicate, track, and trace products along the supply chain with the goal of helping to boost efficiency through enhanced data communication, counterfeit reduction, and drug quality insurance. There are many studies that point to the obvious operational efficiencies and reduction in waste and errors associated with the implementation of RFID-embedded systems (Aldaihani & Darwish, 2013; Azadeh, et al., 2013; Bhamu, Khandelwal, & Sangwan, 2013; Chen, Wu, Su, & Yang, 2008). For example, one main cost for any firm is a lack of knowledge of supply chain integration and how to manage a company's inventory, especially in promoting vendor-managed inventory system and the use of virtual asset trackers (VAT). A company does not want to order as many products as they can and expect it to empty its shelves instantly. By using certain IS applications [automatic identification and capture systems (AIDC) like barcodes, smart cards, touch memory, RFID] aligned with supplier practices, a company can have an improved supply chain performance well into the future ("Healthcare IT outsourcing ...," 2016).

Qrunfleh, Tarafdar, & Ragu-Nathan (2012) provided an empirical based study of how the alignment between supplier management practices and information systems strategy provides a positive association with supply chain integration goals. From their research, as illustrated in Figure 1, IS for efficiency refers to a strategy that is oriented toward operational support of intra- and inter-organizational efficiencies and that the

Figure 1. Using Information systems of increased supply chain efficiencies and flexibilities (partially adapted from Qrunfleh, et al., 2012)

ultimate goal of supplier management practices is to achieve better performance in the supply chain. Ultimately, healthcare organizations have asked their decision makers in strategic positions to evaluate hospitals' need to find ways to support IT and operational functions to deliver high-quality patient care and increase the proficiency of its operations and finances (Devaraj, Ow, & Kohli, 2013). Bottlenecks such as overages in time for surgery, emergency room inflow, and scheduling errors need to be reduced in order to achieve an even and swift process flow.

The above exhibit illustrates some of the interrelationships and interdependencies of supplier practices and different IS strategies that directly affect the supply chain performance of a company. Lean supplier practices consist of activities aimed at creating the most cost efficiency in the supply chain by reducing the inventory and focusing on improving the quality in the supply chain by eliminating waste.

Compared to the alternative of using barcodes, RFID has multiple advantages, which include enhanced traceability and transparency that result in increased operational efficiency (Wambaa, et al., 2013). Moreover, the exchange of data, access to real-time information, and "external and internal coordination of material flows" (Chircu, et al., 2014, p. 738) are key factors to improved efficiency within the supply chain. The collabora-

tion of the manufacturer, wholesaler, pharmacies, and hospitals adds value to the supply chain by reducing errors, and as a result, costs are also lowered. One of the many problems facing the pharmaceutical industry is the persistence of generic and counterfeit drugs as companies try to successfully deal with competition that strategically leverages lower prices. Proper use of RFID technology in supply chain integration issues may offer an alternative to solve these pricing issues. Although using barcodes is cheaper and easier to affix to products, they are not tamper-proof, and it is not possible to read them in bulk, which are two advantages of RFID labels. Ultimately, any transition to new technologies will incur costs. Combining RFID with electronic documents (i.e., e-pedigree) that summarize data about a drug is useful to all supply chain participants. Essentially, it is vital for any organization within any industry to operate as efficient as possible and to search for new ways on how to add value to its processes. RFID can be the solution.

In healthcare settings, RFID can be utilized to manage medication and materials for complex procedures that previously were time consuming and subject to human mismatching errors. One adoption decision was made by Integra's to overcome waste. The use of RFID saved US\$111,500 in lost and missing products and US\$223,000 in expired products (Anand & Wambaa, 2013). Healthcare

professionals, for example, may use RFID readers to access information about medications that can be displayed conveniently on a computer screen.

IMPLICATIONS IN THE HOSPITAL SETTING

Multiple Implications for RFID Technologies in Healthcare

There are multiple implications for RFID technologies in healthcare outside of SCM and supplier integration and performance (Lee & Shim, 2007). In hospitals' workflows in the areas of scheduling, admitting, discharging, and operating can be improved with the implementation of RFID. RFID tags planted in patient bracelets can accommodate information about the patient, such as his or her location, medical history, allergies, age, weight, blood results, diagnosis, living will, and religious preferences. Those bracelets can be utilized in different ways to increase patient safety, operate leaner, and offer improved service (Revere, et al., 2010). For example, RFID bracelets can reduce errors in the billing process. Portable scanners can be used by hospital personnel to scan the patient's bracelet and enter medications administered and services provided. Updated and stored in a database, this information is later used by the billing department to bill the patient. This accuracy leads to faster payments and improved customer satisfaction.

According to one recent study (Southard, Chandra & Kumar, 2012), medical errors lead to a significant amount of deaths. The number ranges between 44,000 and 98,000 per year. Medical errors result in a cost of about US\$2 billion annually. Information on RFID tags in patient bracelets can be used to reduce errors in the administering of drugs by comparing patient information on the bracelets with information on the medication. This reduces errors involving administering the wrong medication or the wrong dosage. Whenever medication is dispensed, the technology can be

utilized to manage inventory levels electronically. Another implication to increase patient safety involves the tracking of operating supplies and materials to avoid surgical tools being "left inside a patient" (Revere, et al., 2010, p.30).

The tracking of patients also results in the reduction of waiting time and an increased efficiency of capacity usage by optimizing bed turnover. As soon as a patient is being discharged from the hospital, an automatic alert can be sent out to housekeeping to prepare the room for a new patient (Revere, et al., 2010). Another improvement concerning time efficiency can be achieved by automatically syncing the computer displays of examination rooms with current patient information as soon as the patient walks through the door. These advances should help reduce miscommunication between physicians and nurses. As the results of the case study concluded, there existed quantitative evidence of the benefits of implementing RFID in healthcare processes by examining surgical processes (Southard, et al., 2012). In one example, it was estimated that nurses typically were spending an average of 15 to 20 mins. per shift trying to locate the proper equipment. Moreover, hospitals waste about US\$50,000 monthly on rental charges because of misplaced or lost equipment. Resulting in about US\$20,000 annually wasted on human resource costs to search for the lost equipment. Other than increased costs, further negative implications include medical equipment missing routine maintenance. In these situations, implementation of RFID can improve the coordination of hospital processes and enhance visibility.

One hospital spent only US\$35,000 on software and US\$50 per active RFID tag. Moreover, it used existing Wi-Fi infrastructure and did not acquire any readers (Southard, et al., 2012). The benefits, transparency and prevention of errors of RFID, outweigh the costs. Again, RFID has two main advantages over barcodes. RFID tags do not have to be physically close to the reader to be read and multiple "pieces of information" can be stored on the tag. This is useful in the supply chain of

pharmaceuticals when tracking and controlling information about temperature, movement, and tampering is important (DesRoches, et al., 2008; Ludwick & Doucette, 2009).

Usage, Application, and Adoption Issues

The usage and application of RFID tags are spreading rapidly and are increasingly spreading into the healthcare industry (DesRoches, et al., 2008; Smith, 2012). Perhaps, the first step in successful implementation of RFID is to perform an initial analysis and needs assessment of how supplier management practices and IS integration strategy tied together to help a company with their supply chain performance practices. The adoption of the RFID-related technology in the healthcare industry has historically lagged behind as compared to other industries in the manufacturing and retail industries, perhaps due in part to certain ethical dilemmas. Many leaders and decision makers of the healthcare industry have begun to realize the role that this technology can positively benefit the industry by maintaining focus on quality care, while doing so by meeting the pressures from competition and achieving business and performance goals (Smith, 2010). The introduction of information technology (IT) into the healthcare industry led to more efficient tasks and processes, a higher quality of healthcare services, and increased accessibility to healthcare providers (Jones, Bekeris, Nakhleh, Walsh, & Valenstein, 2009; Kjøs, Botten, & Romøren, 2008; Palmon & Sudit, 2009; Santouridis, Trivellas, & Reklitis, 2009; Sauerland, 2009; Scanlon, Swaminathan, Lee, & Chernew. 2008; Smith, Casey, Hurst, Fenton, & Scholefield, 2009).

The organizational level of the IT adoption research focuses on the understanding of the diffusion and adoption process. There have been numerous studies that have tried to include as many distinctive characteristics of context as possible in the development phase of organizational IT adoption theories (Domi-

nic, Goh, Wong, & Chen, 2010; Kapur, Gupta, Jha, & Goyal, 2010; Keramati & Behmanesh, 2010; Kim & Tadisina, 2010). Also, researchers have tried to identify the impacts of key categories (i.e., individual, technical, structural, environmental factors, task-related factors) in the adoption process. A number of the previously cited studies that have been done have found that the characteristics of organizations are very significant of the IT adoption process. Another force driving the decision to adopt the RFID process is the environmental factor, “environmental uncertainty, competitive pressure, industrial pressure, and government policy all serve as pressures on organizations (Lee & Shim, 2007, p.714).” Another concept used when deciding whether to adopt the RFID process is the concept of technology-push/ need-pull (TP/ NP); “the technology-push model is based on the view that a new scientific discovery will trigger events ending with diffusion or application of the discovery” (Lee & Shim, 2007, p. 714).

The likelihood of total adoption RFID-related technologies within healthcare organizations is unclear but, it is looking up. Research has showed that RFID is still in the early stages of adopting in the healthcare industry. In a survey done out of 126 organizations (Kumar, Swanson, & Tran, 2009), only 4 are currently using the RFID systems and almost half of those are still planning to evaluate their situation. Also, the results of the survey showed that the adoption rate of the RFID technology is expected to increase since 22 out of 23 that have evaluated RFID processes would adopt it. Applications of RFID-related technologies are inherently very valuable, but some managers feel it is at a great cost to integrate it into a business, at least during their tenure as manager. Healthcare organizations may reap important benefits from RFID application, since it automates the tracking of medical equipment, patients, medical supplies, nurses, and drug usage. These benefits should result in the increase of RFID technology to more than US\$2.1 billion in 2016 (“Healthcare IT outsourcing market ...,” 2014).

Challenges in RFID Application in Healthcare

Even though there are many benefits that should encourage the implementation of RFID technologies in healthcare organizations, the total cost consists of multiple factors that management has to consider before introducing the new system. Adoption and implementation, in addition to maintenance and the training of employees, incur costs. According to a recent case study, the cost of each aspect varies among supply chain partners (Chircu, et al. 2014). RFID-related applications in healthcare involve several benefits; however, there are several challenges that are faced with such a complicated system. Perhaps the most influential challenge are the various costs put into the system, in fact, the high costs of implementing the system into healthcare is what kept the system away from healthcare for so long and kept within commercial applications (Mehrjerdi, 2010, 2012; Smith, 2010).

The concern in the long-term investment is the chance of failure after the expenses have been incurred. It is more likely in RFID for healthcare, but the payoff in RFID is never guaranteed, which is a major concern in adoption in other fields (Erdem, Zeng, Zhou, Shi, & Wells, 2009; Wickboldt, et al., 2012). Mehrjerdi (2011) stated that products that are US \$15 or less may not be worth the costs or return on investment because of the unpromising performance a product would deliver at that low of a price. Infrastructure can also be complex which delays a process that requires patience that some may not think is worth it, since technology is constantly changing and systems are continuously being altered as more information is compiled.

Patient privacy and security is a major challenge in applying RFID to healthcare. Consumer protection programs such as CASPIAN are being implemented because of the possible invasion of privacy to patients (Kapoor, et al., 2009). Patient information is embedded deep within systems;

therefore, patients may be left with a sense of insecurity of their personal information and skeptical of buying into the system. Not only is patient information vulnerable, but also the data concerned with the organization must ensure safety (Wickboldt, et al., 2012). On-the-other-hand, there is a challenge faced with those in control of the RFID trust the system more than the patient, even when that should not be the case. A trusting relationship whether it be between a person and systems, such as patients and physicians trust in RFID renders themselves “vulnerable” (Entwistle & Quick, 2006). Once a healthcare provider has earned the trust from a patient, it is vital that the provider should work even harder to provide the patient with the safety he/he deserves (Entwistle, McCaughan, Watt, Birks, Hall, 2010). Those serving patients with RFID assistance must buy-in to the system; however, the trust must be rational and suitable. Certain situation information is most accurate when it comes from the patient, and if trust is placed in the wrong place, a situation where a patient can contribute the most effectively to their own safety, may be overlooked.

Such as an RFID “VeriMed” system can be thought to attain the “most accurate information” about a patient; however, if the system interpreted information incorrectly such as medications and allergies and the provider trusts the system more than the patient, they may not give it a second look (Monahan, et al. 2011, p.373). Even though a healthcare provider can be well educated and pertain all qualifications for their position there can be differences in the knowledge of the person and the system. Varied abbreviations could be used in a particular organization, and if a provider does not realize that a new system uses a different abbreviation for a medication, it could lead to an overdose or delivery of an incorrect medication (Entwistle, et al., 2006). Therefore, if a doctor trusts the technology to an extent that information within the system is never questioned, then there is the potential for serious medical errors (Fisher & Monahan, 2010).

CONCLUSION

Hopefully, after reading through this chapter, the reader will receive a better understanding of the role that an IS-based strategy, utilizing RFID, and various healthcare supplier management practices do play a significant role on the supply chain performance for a company. Healthcare organizations need to partner and integrate such technologies and medical suppliers in order to strategically leverage each other's strengths to improving the supply chain and better healthcare delivery and related outcomes. A supply chain manager may be very knowledgeable about operational and technological practices to help a company save money by inventory control and production planning, but with the help of RFID-embedded technologies, it has the potential to make the healthcare system operationally run more efficient and effective.

FUTURE DIRECTIONS

Overall the outlook for RFID acceptance is very positive when contemplating the use in supply chain management of medical supplies and pharmaceuticals. Pertinent patient information could prove to be the biggest obstacle to overcome in taking steps of implementation. Managers, healthcare providers, and IT professionals must keep patient concerns in mind when making decisions, conducting training, and processing information. Patients must also be open to the use of RFID in order to reduce medical errors. The reduction of these errors can be critical and life-saving. The use of these case studies will continue to provide evidence supporting the use of RFID in healthcare.

KEY TERMS AND DEFINITIONS

Automatic Identification and Data Capture Technologies (AIDC): Types of AIDC-related technologies to leave the human element out of the data collection and storage functions of information derived from manufacturing, integrated through the manufacturing process, types of authentication concerns and/or e-security strategies, and relationship links to customer profiles.

Barcoding Technology: A long-term and very reliable type of AIDC technology, it is known for its very accurate and economical approaches to identity products and machine readable information from a variety of manufactured goods and services. Most barcodes use a type of standardized bars and spacing coding or symbology that is certified by an international standards body (GS1 System).

Ethical Dilemmas: There are a number of ethical theories that are appropriate for dealing with healthcare issues concerning automatic identification. These theories involve both individual and group behaviors that are grounded in moral philosophy, especially in the concepts of consequentialism or deontology ethical philosophy.

Healthcare Service Strategies: When it comes to the healthcare industry, an overall strategic goal is to provide affordable coverage and quality service to all citizens that need such services at affordable costs.

Operations Efficiency: Improving efficiency and reducing waste is a major challenge for hospitals and other patient care facilities looking to lower the cost of providing healthcare services.

RFID-Embedded Technologies: RFID technologies are types of automatic data capture techniques that use a combination of active and passive senders and receivers to collect and store codified information for further uses.

Supply Chain Management/Performance: In basic terms, supply chain is the system of organizations, people, activities, information and resources involved in moving a product or service from supplier to customer. The configuration and management of supply chain operations is a key way companies obtain and maintain a competitive advantage.

Vendor-Managed Inventory Systems (VMI): VMI-based systems are designed to transfer the control of inventory and its planning activities to a manufacturer or distributor in order to provide a beneficial relationship to promote a more transparent and seamless flow of goods and services at lower costs.

Virtual Asset Trackers (VAT): VAT is a type of application of active RFID tagging that allows healthcare practitioners to enhance security to patients, residents, and hospital staff while providing better patient and resident-care services.

M

Social Telerehabilitation

Gilberto Marzano

Rezekne Academy of Technologies, Latvia

INTRODUCTION

In a relatively short time, information and communication technologies (ICT) have spread worldwide, from defense and space exploration to large industrial applications, and to the worlds of commerce, education, and entertainment. ICT is changing people's daily lives, the way they work, buy, sell, and learn, and also the way that services are run in the healthcare sector. Consequently, *e-health*, *telehealth*, and *telemedicine* are now terms that are commonly used in this sphere, encompassing three main computer-assisted areas in healthcare, namely: clinical assessment, diagnosis, and therapy. E-health comprises the monitoring of patients' health, the promotion of good practices, and the prevention and treatment of health conditions by electronic means, as well as the provision of online access to literature and medical knowledge. One of the first reviews of telehealth is that provided by Winters (2002), who identified two major subsets of telehealth: telemedicine (i.e., delivery of clinical services) and telehealthcare (i.e., management of disability and health).

Nowadays, there is a progressive specialization within the field of e-health, and the specificity of the different branches appears to be increasingly sharp.

Telerehabilitation is a recent emerging field in telehealthcare area and this chapter presents social telerehabilitation, a new specialized sector of telerehabilitation.

BACKGROUND

Before to deal with social telerehabilitation, the more general notions of rehabilitation and telerehabilitation ought to be introduced.

In fact, social telerehabilitation, which focuses on solving limitations and social issues associated with health conditions, represents a further specialization in telerehabilitation. Figure 1 shows the position of social telerehabilitation within the general framework of telehealth.

It has to be noted that social telerehabilitation results from a change in the concept of rehabilitation, which has seen a shift in view point away from a predominantly medical one, towards an

Figure 1. Social telerehabilitation within the telehealth general framework

DOI: 10.4018/978-1-5225-2255-3.ch516

increasingly complex one in which psychological and socio-cultural aspects are deemed to be of equal importance (Brown & Hughson, 1993; Wade & de Jong, 2000; Altman, Swick, Parrot & Malec, 2010; Karkou, Martinsone, Nazarova & Vaverniece, 2011).

The Notion of Rehabilitation

In general, rehabilitation encompasses any services or providers that are directed to the reduction of impairments, activity limitations, or social participation restrictions experienced by an individual (Figure 2). The World Health Organization describes rehabilitation for people with disabilities as being a process aimed at enabling them to reach and maintain their optimal physical, sensory, intellectual, psychological, and social functional levels.¹

Generally, two different forms of rehabilitation can be distinguished: *medical* and *social*, or, in the latter case, also referred to as *vocational*.

Both forms are aimed at developing the functional and psychological abilities of the individual and, if necessary, his/her compensatory mechanisms, in order to enable him/her to attain self-dependence and lead an active life. The main

difference between them is that medical rehabilitation is more restricted to curative medicine, and involves intensively trained clinicians and different health professionals, especially physiotherapists, whilst social rehabilitation focuses more on the individuals' social sphere, and includes services such as rehabilitative nursing, occupational therapy, speech and language therapy, audiology, dietetics, prosthetics and orthotics, podiatry, art therapy, music therapy, and social work. However, although social rehabilitation is directed, for example, at overcoming barriers for people to access, maintain, or return to employment or other useful occupations (ILO, 2008; Kuoppala & Lamminpää, 2008), it substantially differs from strategies and policies aimed at promoting and developing the inclusion of people with disabilities in the work place. Offender rehabilitation (Robinson & Crow, 2009) and addict rehabilitation (Wilson *et al.*, 2012), for example, are considered to be forms of social rehabilitation that focus on the development of practices and programs for helping individuals to retake their place in society.

Many social scientists and policy makers share the opinion that community-based rehabilitation practices are a part of general medical care (Haig, 2013). As a consequence of this, it is not always

Figure 2. The rehabilitation process

possible to trace a line of demarcation between clinical and social rehabilitation, and sometimes there is an overlapping relation between these two forms of rehabilitation. A case in point is the *Report on Disability* (WRD) of June 9th 2011, published by the World Health Organization (WHO) and World Bank (WB), which outlined concrete actions that befit both medical and social rehabilitation.

Such concrete actions intended to help overcome barriers to the provision of rehabilitation services (WHO & WB, 2011) include:

- Increasing human resources for rehabilitation (training, retaining, and retention of rehabilitation personnel);
- Expanding and decentralizing service delivery;
- Increasing the use and affordability of technology and assistive devices.

It has been observed that the WRD report presents a challenge to medical rehabilitation (Bethge, von Groote, Giustini & Gutenbrunner, 2014) and, although it doesn't provide a fixed definition of rehabilitation, its description of the concept represents a valuable frame of reference that can help to foster a common understanding of the rehabilitation scope and rehabilitation services (Meyer, Gutenbrunner, Bickenbach, Cieza, Melvin & Stucki, 2011). In fact, many authors cite in their works the WRD definition of rehabilitation, that being: "a set of measures that assist individuals who experience, or are likely to experience, disability to achieve and maintain optimal functioning in interaction with their environments" (Meyer et al., 2014; Lynggaard, May, Beauchamp, Nielsen & Wittrup, 2014; Gibson, 2016).

It is important to note that the WRD definition recalls that of Article 26, entitled *Habilitation and Rehabilitation*, of the United Nations Convention on the Rights of Persons with Disabilities (CRPD, 2006):

*[...] appropriate measures, including through peer support, to enable persons with disabilities to attain and maintain their maximum independence, full physical, mental, social and vocational ability, and full inclusion and participation in all aspects of life.*²

The above definitions fit well with both medical and social rehabilitation, as well as with telerehabilitation that includes social telerehabilitation.

Telerehabilitation

The term "telerehabilitation" is a relatively new one, although it has been observed that the first experiment with remote medical interventions dates back to the 1880s, following the invention of the telephone (Scalvini, Vitacca, Paletta, Giordano & Balbi, 2004).

Until a few years ago, telerehabilitation applications were considered within the wider field of e-health, and only recently telerehabilitation has been assumed to have an autonomous, separate, and parallel identity under the telehealth umbrella, within telehealthcare (Schmeler, Schein, McCue & Betz, 2009).

Essentially, telerehabilitation comprises methods of delivering rehabilitation services using ICT to minimize the barriers of distance, time, and cost, and, more specifically, has been defined "as the application of telecommunication, remote sensing and operation technologies, and computing technologies to assist with the provision of medical rehabilitation services at a distance" (Cooper et al., 2001).

Social Telerehabilitation Definition and Scope

Both telerehabilitation and social telerehabilitation are grounded in the delivery of rehabilitation services through telecommunication networks, especially by means of the Internet. Likewise,

one can define social telerehabilitation as being the application of ICT to provide equitable access to social rehabilitation services, at a distance, to individuals who are geographically remote, and to those who are physically and economically disadvantaged.

The scope of social telerehabilitation is vast, since it faces challenges related to both medical and community care settings (Hill, 2010). Social telerehabilitation aims at helping people regain their psycho-physical functions and improving their daily quality of life through the use of ICT and mobile technologies (Reeder, Chung & Stevens-Lapsley, 2016; Kamwesiga, Tham & Guidetti, 2016). In this regard, research has underlined the potential and effectiveness for social media, mobile phones, and the Internet in general, to improve social rehabilitation processes.

Expanding and Decentralizing Rehabilitation Services

Telerehabilitation and social telerehabilitation share the same goal: to expand and decentralize rehabilitation service delivery.

In fact, both medical and social rehabilitation services are generally located in urban centers and health care structures, and this hinders their access by people with disabilities or those living in rural areas. In many cases, the burden of transportation, as well as the mobility assistance for persons with temporary or chronic diseases, represents a serious barrier that limits the advantages of rehabilitation services. Parking, distance, or transportation difficulties can significantly interfere with the receiving of treatments. In fact, the more frequent the treatments are, the more the mobility burden increases.

Furthermore, in the majority of cases, rehabilitation, either medical or social, involves multidisciplinary professional competence and expertise (Neumann et al., 2010; Stanos, 2012; Malladi, 2015). This means that the planning activity and the actual treatments involve teams of professionals (physiotherapists, psychologists,

social educators, etc.) who must work together in order to achieve common and complementary goals. Their activity is directed to resolving the patient problems, following an iterative, active, educational, and problem-solving process that focuses on the patient's behavior and adapts to it (Marzano, Lubkina & Rizakova, 2015). The most common goals of the rehabilitation process are:

- Maximizing the participation of the patient in his/her social setting;
- Minimizing the pain and distress experienced by the patient;
- Minimizing the distress of, and the stress on, the patient's family and caregivers.

Accordingly, telerehabilitation is particularly useful when the coordination of rehabilitation service delivery requires the improvement and expansion of the availability of coordinated multidisciplinary rehabilitation in an effective care framework.

Both social and medical telerehabilitation services are generally provided on an outpatient basis, usually at home and under the supervision of at-a-distance professionals. Experts check patient evolution through regular online meetings or by analyzing data from sensors and equipment. Depending on the telerehabilitation programs, there are many kinds of assistive devices whose cost is lowered by mass production, e.g. there are many very affordable teleconference systems, and mobile phones are used for remote data collection, control of equipment, and telemonitoring. Supervisors can help the patient to perform exercises during the day-to-day rehabilitation sessions, suggesting the correct execution.

In the last few years, many researchers and practitioners have argued the importance of social telerehabilitation services for patients, caregivers, and public institutions, for instance in regard to services for children suffering from physical handicaps and emotional disturbances (Nilsson & Nilsson, 2011b), alcoholics (Simpson, T. L., Kivlahan, Bush & McFall, 2005; Rose, Skelly,

Badger, Naylor & Helzer, 2012), and for patients with affective disorders, such as depression and manic-depression or bipolar disorder (Sachpazidis & Sakas, 2008; Acampora, Cook, Rashidi & Vasilakos, 2013).

Research has underlined the potential for social media, mobile phones, and the Internet in general, to improve mental and physical health, treat addictions, and also to help individuals experiencing homelessness (Quan, Joseph, Keller & Arch, 2011; McInnes, Fix, Solomon Petrakis, Sawh & Smelson, 2015). Furthermore, Artificial Intelligence is discovering new opportunities to overcome the limitations of the computational approach and, consequently, making possible new advanced healthcare applications, especially in the social-healthcare (Pravettoni, Folgieri & Lucchiari, 2015).

Application of Social Telerehabilitation

It has been underlined that social telerehabilitation tackles some issues that set it apart from the broader telehealthcare arena. For example, it has been observed that one challenge is that social rehabilitation is often provided across both medical and community settings, often with different funding structures and rehabilitation protocols in place (Scaffa & Reitz, 2013; Camicia, Black, Farrell, Waites, Wirt & Lutz, 2014).

From the analysis of the literature, three principal areas of interest emerge in terms of the development of social telerehabilitation services:

1. The psycho-physical area;
2. The social-communication area;
3. The behavioral area (e.g. behavioral addictions).

Applications are available for health education and counseling programs, many of them offered to myocardial infarction patients during and after hospitalization. During hospitalization, the inter-

ventions consist of individual counseling sessions and group health education sessions focusing on medication, healthy habits, and anxiety and depression. After discharge from hospital, patients are checked at home by telephone or via the Internet, and are encouraged to perform exercises and physical activity. Social telerehabilitation programs demonstrate their effectiveness in the areas of decreasing unhealthy eating habits, cessation of smoking, and treating anxiety and depression of patients following a stroke (Beatty, Fukuoka & Whooley, 2013; Varnfield et al., 2014).

A Typical Social Telerehabilitation Service for Elderly Who Need Physical Exercises

To better understand how social telerehabilitation processes operate, we can illustrate a typical example of a telerehabilitation service that concerns physical exercises for elderly people.

The first step is the identification of needs and the recognition of related problems: the social rehabilitators' team performs the evaluation of the elderly person conditions in order to verify his/her capability to benefit from the service. Professionals engaged in the rehabilitation program use teleconference and/or phone communication to discuss the case and define the rehabilitation program, and to generate its electronic workflow. Following this, the trainer demonstrates exercises to the patient, and answers his/her queries and clears his/her doubts. This step can be performed either at a distance or face-to-face. The trainer then conducts videoconferencing sessions for the progression of exercises, supervision of program completion, additional demonstrations, and consultations. As may be the case, exercises might include flexibility, strength, endurance, and other types of active motion activities. For videoconferencing, a professional videocamera and Skype software with a broadband internet facility can be used. The patient is regularly engaged in exercises and followed by the same trainer, who

will give him/her instructions, e. g. in order to adjust the video camera for each exercise, number of repetitions, etc.

Online delivery of social rehabilitation services encourages the rethinking, reorganization, optimization, and extension of the current social rehabilitation services that fall under face-to-face treatments and protocols. Of course, this can require the retraining of rehabilitators

In general, a social telerehabilitation system should provide patients and caregivers suitable mechanisms to interact with each other as if they were meeting face-to-face. Furthermore, patients should have at their disposal all the information about the schedule of the rehabilitation plan, a full description of the rehabilitation activities, and real-time feedback about their performance. For rehabilitators, the system should gather information about the fulfillment of the program, and the correctness of the patients' performance. This will allow a quick and ubiquitous assessment of the patients' evolution, and an adjustment of their rehabilitation program if necessary.

A social telerehabilitation system includes:

- Computers and other general-purpose devices (i.e. tablets, laptops, videocameras, and so on), for both patients and rehabilitators, which are used to run the applications.
- Different types of sensors used to monitor the patient's performance; the simplest of them being low-cost wearable motion capture devices (e.g. accelerometers that gather values of linear acceleration along three perpendicular axes (x, y, z)).
- Specific software application, e.g. for social-cognitive exercises, speech therapy, etc.

FUTURE RESEARCH DIRECTIONS

The idea of exploiting ICT in psychosocial care is not a novelty. Eliza, the computer program created by Weizenbaum between 1964 and 1966 (Weizen-

baum, 1966), can be considered to have been a primitive attempt at social telerehabilitation. It was a tongue-in-cheek application, which emulated the responses of a Rogerian non-directional psychotherapist during an initial psychiatric interview. Since then, much progress has been made to the point that social telerehabilitation now represents a topical field of research.

Almost 50 years have passed between the creation of the Eliza program and the appearance of the recent programs designed for rehabilitation services. The difference between the two is that Eliza was one of the first experimental programs in the field of natural language processing, whilst the new electronic applications are able to utilize the achievements made in natural language processing for communicating with patients. The focus is now on programming machines for empathy emulation and ethical therapeutic activities. One of the next future challenges is to provide robotic caregivers for social rehabilitation purposes.

In fact, thanks to the investigations that have started in the last fifteen years on different forms and roles of affection in virtual agents and robots (Scheutz, 2011), some researchers are now considering the employment of robots in social rehabilitation services (Tickle-Degnen, Scheutz & Arkin, 2014). The new robots could provide moral functionalities that enable them to establish therapeutic human relationships, for example in the context of occupational therapy and Parkinson's or Alzheimer's disease (Salichs, Encinar, Salichs, Castro-González & Malfaz, 2015). At the simplest level, a robot could ensure basic functional elements of interpersonal communication. On a more sophisticated level, they could act as *observers* that accurately detect and prioritize people, objectives, and context attributes relevant to reasoned and ethical therapeutic interaction (Arkin, Scheutz & Tickle-Degnen, 2014).

Furthermore, the applications of wearable technology to monitor older adults and subjects with chronic conditions at home and in community settings are multiplying, while the integration of wearable and ambient sensors is expected to make

Figure 3. Future caregiver robot

Future caregiver robot	
Key characteristics	
•	Embodiment
	Representation independent
	Situadness (social behavior)
	Emergent complexity (collective action of different agents)
	Real time responses

relevant progress (Patel, Park, Bonato, Chan & Rodgers, 2012).

Finally, behavior-based caregiver robots represent a social telerehabilitation new advanced research area that presumes interaction among a machine and a human patient. The keystone concepts behind the artificial behavior-based caregivers are showed in Figure 3.

However, at next future, we are left with some as yet unresolved questions concerning social telerehabilitation:

1. To what measure can social telerehabilitation replace traditional face-to-face social rehabilitation therapies?
2. Which are the priority sectors for intervention?
3. Is social telerehabilitation in these sectors really economical?
4. What is the educational effort and cost that would be required to diffuse knowledge about social telerehabilitation practices?

A broad, coordinated, research effort will be needed to provide answers to the above questions.

CONCLUSION

The use of computers to deliver traditional social rehabilitation services cannot be a sufficient condition for transforming them into effective social telerehabilitation services: to make these services really effective, it is often necessary to both rethink them in the light of the opportunities

offered by the new technologies and, at the same time, to carefully analyze the impact that they have on the persons involved in the process. In many cases it is worthwhile to verify the impact on the organization which delivers social telerehabilitation services, e.g. considering the requalification of personnel, the reliability of the computing services, the costs, and so on.

Internet-based applications can be realized not only for follow-up communications between caregiver-doctor-patient after a therapy, which is the most common use of ICT in the rehabilitation process, but also for improving the quality of the traditional rehabilitation therapies, or for realizing services that are entirely new.

The aim of developing new types of services is shared by social innovation. Another common point between social innovation and social telerehabilitation is that both entail cutting across organizational, sectoral, or disciplinary boundaries of expertise. Furthermore, social innovation looks towards technology as a means to create new social relationships between previously separate individuals and groups.

Social innovation and social economy are closely related: both pursue the same goal of creating solutions that can generate a positive impact, not only on the economic but also on the social development of people and their communities. The basis of social economy is the creation of services that focus on specific target groups who need to be sustained and assisted (e.g. services that complement core hospital staff, employment counseling, vocational training, education/rehabilitation for addict/misfit people, and so on), or that satisfy a general public need (e.g. nurseries, care services for the elderly, shelters for the homeless, integration for the disabled, and so on).

Social telerehabilitation can primarily be useful in the above-mentioned sectors, especially in the scope of social rehabilitation applications related to the labor sector. In this case, social telerehabilitation needs to be underpinned by an integrated approach and by a strong collaboration among different subjects, namely: rehabilitation

structures, employers, and workers. Education institutions play a crucial role in the implementation of social telerehabilitation services since the different subjects involved in them need to be educated. More generally, though, telerehabilitation and social innovation necessitate training and retraining activities for both the providers and users of services.³

KEY TERMS AND DEFINITIONS

Artificial Intelligence: Is a branch of computer science that aims to improve machine behaviour in tackling complex tasks that are specific of human beings.

Behavior-Based Robots: Are implemented following an approach that focuses on exhibiting in a robot complex-interactive behaviors in given environment.

Caregiver: Is someone who (paid or unpaid) takes care of another person who is either sick or disabled; a caregiver is most commonly used to address impairments related to old age, disability, a disease, or a mental disorder.

Occupational Therapy: Helps to solve the problems that interfere with an individual ability to do the things that are important to them; it can also prevent a problem or minimize its effects.

Problem Solving Process: Consists of using methods, in a methodical and organized manner, for finding solutions to problems.

Social Educator: Is an independent and recognized professional figure linked to the area of social professions; he supports and guides a person with developmental disabilities in making his or her own choices and implementing their decisions.

Wearable Technology: Consists in incorporating in clothing computer and advanced electronic technologies.

World Bank (WB): Is an international financial institution that provides loans to developing countries for capital programs.

World Health Organization (WHO): Is a specialized agency of the United Nations that is concerned with international public health.

A Validation Study of Rehabilitation Exercise Monitoring Using Kinect

M**Wenbing Zhao***Cleveland State University, USA***Deborah D. Espy***Cleveland State University, USA***Ann Reinthal***Cleveland State University, USA*

INTRODUCTION

In rehabilitative health care, a carefully designed physical exercise plan could be instrumental to the recovery of a patient provided that the patient. Exercise programs are prescribed to address specific problems, and are often individually tailored by a clinician due to the presence of co-morbidities and additional impairments. It is critical that the patient perform the proscribed program correctly and with adequate practice repetitions (in the range of thousands) (Kleim and Jones, 2008), otherwise, the exercise may be ineffective, or even dangerous (Escamilla et al., 2009; Tino & Hillis, 2010).

Correct adherence to supplemental home exercise is essential for safe, effective, and efficient care. The lack of correct feedback during independent in-home exercise is therefore a serious concern. The use of simple counting devices helps verify the exercise repetitions. However, such simple, commercially available devices cannot fully capture all the required movements beyond the most simple, such as counting steps or recording overall amounts of activity (Wagner et al., 2012; Yang & Hsu, 2010), and are, therefore not useful for most prescribed home exercises.

The release of the Microsoft Kinect sensor, which is equipped with a depth camera capable of measuring 3 dimensional positions of the objects in its view, has triggered tremendous interest in its use to monitor in-home physical therapy exercises

(Chang et al., 2013; Chang et al., 2012; Garcia et al., 2012; Gibson et al., 2012; Guerrero & Uribe-Quevedo, 2012; Huang, 2011; Zannatha et al., 2013; Pastor et al., 2012). A Kinect-based system could facilitate proper performance of the exercise or fitness program, increase patient accountability, allow the clinician to correct any errors in exercise performance, and allow program modification or advancement as needed. Hence, the Kinect sensor based system could potentially provide sufficient feedback and guidance to patients performing clinician prescribed in-home exercises, significantly minimizing costly and inconvenient trips to outpatient centers, and improving the effectiveness and outcomes of courses of treatment.

Many existing clinical trials with Kinect-based systems appear to have proceeded without comprehensive validation tests (Chang et al., 2013; Chang et al., 2012; Garcia et al., 2012; Gibson et al., 2012; Guerrero & Uribe-Quevedo, 2012; Huang, 2011; Zannatha et al., 2013; Zhao et al., 2014; Tamei et al., 2015; Ebert et al., 2015). Other studies have aimed to characterize the accuracy of the Kinect sensor; however, these validation studies have focused primarily on the movements within the frontal plane for a subset of the joints or segments (Clark et al., 2013; Obdrzalek et al., 2012; Mobini et al., 2013). In this article, we report our validation study on using a Kinect-based system for physical therapy exercise monitoring. Instead of comparing the joint positions or angles

DOI: 10.4018/978-1-5225-2255-3.ch517

formed by key segments with respect to a (usually far more expensive) reference system, we take a completely different approach by focusing on the feasibility of using such a system to assess the correctness rules for a few common exercises in physical therapy. The correctness rules are readily implementable in a computer program for real-time motion tracking and feedback.

Due to space limitation, we only present results for two exercises, namely hip abduction and toe touch. In the standing hip abduction exercise, one leg is moved into hip abduction without any additional sagittal plane hip flexion/extension or transverse plane hip rotation. The pelvis, knee, and ankle remain stationary. In the standing toe touch exercise, the trunk bends forward and the arms reach to touch the floor. Motion occurs primarily as sagittal plane spine and hip flexion with concurrent shoulder flexion. When done correctly, there is minimal movement of the elbows, wrists, knees and ankles. We show that, although the Kinect-based system is capable of assessing many correctness rules for these exercises, it fails in the presence of significant self-occlusion, especially for the toe-touch exercise.

BACKGROUND

Microsoft Kinect was initially released as an add-on device for the Xbox 360 game console. Kinect enables a person to interact with a game using gestures and voice commands via what is referred to as the Natural User Interface. In early 2011, Microsoft released an official driver for Kinect and a software development kit (SDK). The most useful feature of the SDK is skeletal tracking, via which, an application can receive pre-processed frames containing up to two skeletons each with 20 joints for Kinect v1, and up to four skeletons each with 26 joints for Kinect v2 (Lun and Zhao, 2015). Also very useful in the Microsoft Kinect SDK are its floor clipping application programming interfaces (APIs). Each skeleton frame includes a floor clipping plane vector containing

the coefficients of the floor plane equation. Based on the floor clipping plane vector, we can calculate the vertical height off the floor clipping plane of each joint. In our study, we exploited the APIs to assess the correctness of some of the exercises.

VALIDATION STUDY

To validate the use of Microsoft Kinect for rehabilitation monitoring, we compared the skeletal joint results obtained from Kinect to those obtained concurrently by a Cortex motion capture system (Motion Analysis Corp, Santa Rosa CA) (2010). The subjects wore a full Helen Hayes marker set and each exercise was recorded by 8 cameras. The Cortex motion results were used to establish the ground truth for the study according to its established accuracy.

Our study has gone through three phases. During the initial phase, we attempted to carry out a mechanical point-to-point comparison between the two systems based on coordinate transformation. This proved to be difficult because it would require the Kinect sensor to be placed in a known location and a known tilt angle to the Cortex system. In the second phase, we attempted to focus on the comparison of relative movement between joints and the angles formed between adjacent segments during the movement. This effort was partially successful because it did not require coordinate transformation. However, a comprehensive comparison was still difficult because the positions of the markers used in the Cortex system did not correspond strictly to the joint positions reported by the Kinect sensor. Figure 1 shows a partial comparison of results we obtained in the first two phases for the hip abduction study. By exploiting the floor clipping plane APIs, we managed to compare the height of the knee and ankle during the hip abduction motion (i.e., right knee and right ankle) reported by the Kinect sensor and that captured by the Cortex system. As shown in Figure 1(b), the Kinect results were fairly close to those captured by the Cortex system. Figure

Figure 1. A comparison of the Kinect measurement and that from the reference motion capture system in early stages of this study. (a) The angle formed by the two legs in hip abduction. (b) The height of the right (abducting) knee.

1(a) shows the angle formed by the two legs as reported by Kinect and the Cortex system. Again, we can see that the Kinect results were very close to those captured by the Cortex system.

Although the early results proved promising in using Kinect for therapeutic exercise monitoring, they were far from comprehensive. After all, the correct angle or the correct trajectories of particular joints do not necessarily mean an exercise is done correctly. We needed to perform a system-level assessment of Kinect's feasibility. We believe the most appropriate way to examine whether Kinect can be used to tell if a patient is doing an exercise correctly is based on a set of pre-defined correctness rules. Such rules establish a set of invariance for each exercise with appropriate error bounds. We argue that this approach is far more practical compared with the mechanical point-by-point based assessment:

- The point-by-point based approach would require: (1) a coordination systems translation between the Kinect coordinate system and that used by the reference motion capture system; and (2) the reference system joint positions derived from external marker placements to match those reported by the Kinect SDK. In our experiences, neither is trivial.
- Typically, prescribed therapeutic exercises allow a range of movement speeds and trajectories according to predefined correctness rules. As such, even if the joint positions reported by Kinect contain error, they might be adequate to assess whether or not the rules have been followed by the patient. Furthermore, some rules are more strict than others. A 5 cm error in Kinect measurement for a particular joint might not impact the assessment of the correctness for one exercise, but might blur the correctness boundary for another. Therefore, what matters ultimately is whether or not we can use a Kinect based system to distinguish correct exercises from wrong ones.
- Similarly, self-occlusion happens frequently during an exercise when a single Kinect camera is used. The positions for the occluded joints are estimated in Kinect. Hence, such joint positions are inevitably inaccurate. However, whether or not a large error for an occluded joint matters depends on the correctness rules for each exercise. The point-by-point based validation approach cannot give us a definitive answer as to whether or not Kinect is useful because such validation is without context.

In the following subsections, we report our experimental validation results for two typical physical therapy exercises, namely, hip abduction and toe touch.

Hip Abduction

For the hip abduction exercise, typically the following 7 rules are used to evaluate if a patient is doing the exercise correctly. Throughout, we assumed that the left leg is stationary and the right leg is the abducting leg:

Rule 1: Weight shift onto the left leg prior to abducting right leg.

Rule 2: The left leg is straight and leans slightly left after the weight shift and during right leg hip abduction.

Rule 3: Upper body shifts to the left side over the left leg after the weight shift and during right leg hip abduction.

Rule 4: Arms are held out in the frontal plane.

Rule 5: The right leg stays in frontal plane during hip abduction.

Rule 6: The right foot remains pointing forward during hip abduction.

Rule 7: The pelvis stays stable after weight shift and motion occurs only at the hip joint.

To assess the rule 1 conformance, we measured the angle formed by the following two vectors:

(1) a vector from the left ankle to the left hip joint *obtained in the initial pose*, and (2) a vector from the left ankle joint to the center of mass of the patient. Ideally, the angle should be reduced to 0 when the weight is completely shifted to the left leg. As can be seen in Figure 2, the angle calculated from the Kinect measurement clearly shows a gradual reduction from about 4.5 degrees to less than 1 degree, and it is very consistent with that measured by the Cortex system, although noticeably more noisy.

Rule 2 has two components: (1) the left leg must remain straight, and (2) the patient leans slightly left. Component (1) can be easily assessed by measuring the angle formed between the left knee to left hip segment and the left knee to the left ankle segment (referred to as left knee angle), and component (2) can be characterized by a leaning angle defined as the angle formed between the left hip to the left ankle and the vertical line from the left hip to the floor. Ideally, the left knee angle should remain at 180 degrees and the lean angle should change from 0 to a small value.

During our experiment, the subject performed 5 iterations of hip abduction with the first 3 iterations performed correctly and the last 2 intentionally violating rule 5 (the very last iteration is partially captured). As shown in Figure 3(a), the left knee angle as measured by Kinect stays within 170-180 degrees. The measurement result from the Cortex system reveals slightly larger variations

Figure 2. A comparison of the weight shift angle for hip abduction

(from about 160-180 degrees). The leaning angle indeed starts from about 0 degrees to an average of about 8 degrees for both the Kinect and Cortex measurement results as shown in Figure 3(b). However, the Kinect data are much noisier than the Cortex results. Nevertheless, the results showed that with appropriate error bounds, the Kinect based system can be used to assess rule 2 conformance.

Rule 3 is evaluated by measuring the angle formed between the shoulder center to hip center vector and the same vector at its initial position. This upper body shift angle should start at 0 and increase to a moderate angle. In between two iterations of the hip abduction, the angle should reduce to a smaller angle. As can be seen, this was indeed the case as measured by both the Kinect and the Cortex systems as shown in Figure 4. The maximum shift angle as measured by the Cortex system was clearly bigger than that measured by the Kinect based system, indicating a systematic error in the Kinect measurement. Fortunately, this systematic error is relatively small, about 2 degrees for correct iterations and as large as 6 degrees for incorrect iterations. We believe such small error is acceptable for assessing rule 3.

Rule 4 is concerned with the placement of the arms during hip abduction. There are two com-

ponents to the rule: (1) both arms must remain in the frontal plane, and (2) both arms must move out. To assess this rule, we must first establish the frontal plane, accomplished by using the following two vectors: (1) hip center to the left shoulder, and (2) hip center to the right shoulder. More specifically, the frontal plane was established by using the two vectors obtained in the *initial* T-pose. We calculated the out-of-frontal-plane angle of each arm. Ideally, the angle should remain 0. When an arm is moved out, it would form a 90 degree angle with respect to the torso (represented by a vector from shoulder center to the hip center). Due to the weight shift and leaning during abduction, the angle would oscillate around 90 degrees.

As shown in Figure 5(a), both arms remained within about 10 degrees from the frontal plane according to the Cortex system. As measured by the Kinect based system, the left arm indeed stayed within 10 degrees of the frontal plane; however, the right arm appeared to deviate from the frontal plane by as much as 25 degrees. This indicated that we would need a fairly generous error bound to assess rule 4 using the Kinect based system. As shown in Figure 5(b), the arms deviated from 90 degrees by as many as 10 degrees according to the Cortex system. While the arm-to-torso angles measured by the Kinect based system showed

Figure 3. A comparison of the left knee angle and leaning angle for hip abduction rule 2 assessment

Figure 4. A comparison of the upper body shift angle for hip abduction hip 3 assessment

Figure 5. A comparison of the upper body shift angle for hip abduction rule 3 assessment

smaller deviations from 90 degrees, they were apparently systematically larger than those measured by the Cortex system by approximately 10 degrees. Nevertheless, this systematic error does not appear to limit the use of Kinect to assess the second component of rule 4 for hip abduction.

Rule 5 can be assessed very similarly to the first component of rule 4. We calculated the out-of-frontal-plane angle formed between the right leg and the frontal plane. For correct iterations, this angle should be near 0 degrees, and should have significant non-zero angle values for the incorrect iterations. As can be seen Figure 6, according to

the Cortex system, the out-of-frontal-plane angle for the right leg oscillated slightly around 5 degrees with an amplitude of about 5 degrees for the 3 correct iterations, and increased to over 30 degrees off the frontal plane for the incorrect iterations. The Kinect data showed that the oscillation was around 8 degrees (instead of Cortex's 5) for correct iterations and the amplitude about 8 degrees (instead of 5). This error in Kinect measurement can be easily overcome by setting slightly larger error bounds when assessing the hip abduction exercises in practice. For the wrong iteration, the highest angle captured by Kinect was very con-

sistent with that measured by the Cortex system at about 32 degrees. Hence, it is clear that Kinect is capable of detecting the violation of this rule.

For rule 6, we measured the angle formed between the ankle-to-foot vector and a forward-pointing vector. The forward-pointing vector was perpendicular to the frontal plane and can be easily derived from the cross product of the hip-center-to-left-shoulder vector and the hip-center-to-right-shoulder vector. If the foot is indeed pointing strictly forward, the angle should be 0.

As shown in Figure 7, the right foot is, in fact, not even close to 0 degrees. According to the Cortex system, the foot angles varied around 30 degrees. The Kinect data showed very large variation, between 20 and 70 degrees. Our experiments clearly show that Kinect is not capable of assessing this rule due to the inaccuracy of the measurement for the foot segment.

Rule 7 is not assessable by the Kinect based system because the current Kinect SDK does not provide APIs to capture the motion of the pelvis.

In summary, the majority of correctness rules can be assessed by a Kinect-based system. However, we note that rules for subtle movements, such as the foot alignment and pelvis movement, cannot be evaluated by Kinect. If these movements are critical for some physical therapy exercises,

either the Kinect's capability has to be expanded and improved, or other motion capture systems would need to be used.

Toe Touch

For the toe touch exercise, typically the following 4 rules are used to evaluate if a patient is doing the exercise correctly.

Rule 1: Both knees are extended, i.e., the legs are straight.

Rule 2: The torso should not rotate as the fingers reach for the floor.

Rule 3: Ankles should not move.

Rule 4: Feet are pointed forward.

We can assess rule 1 by measuring the angle formed by the upper leg and the lower leg. If the legs are straight, then the angle should be at 180 degrees. As shown in Figure 8, for a toe touch run with two iterations, according to the Cortex system, both legs were indeed fairly straight as the knee angle stayed very close to 180 degrees. Unfortunately, the angles calculated from the Kinect data were far off 180 degrees when the subject's torso occluded the legs when his fingers reached for the floor. This clearly shows that we

Figure 6. A comparison of the angle between the right leg and the frontal plane for hip abduction

Figure 7. A comparison of the angle between the right leg and the frontal plane for hip abduction

cannot use Kinect to properly evaluate rule 1 conformance before the self-occlusion problem is resolved.

When the torso does not rotate during the movement, the left and right shoulder should move within the sagittal plane in parallel. Hence, the traveled distance from its initial position should be the same for the left or right shoulder joint. Therefore, we assessed the rule 2 conformance by measuring and comparing the distance travelled relative to the initial position (in T-pose). If the torso does not rotate, the distances for the left and right shoulders should be the same. As can be seen in Figure 9(a), this was the case for

a correct iteration of toe touch. For an iteration with torso rotation, the distances were different, as revealed in Figure 9(b).

Note that there were apparent discrepancies in the distance measurement results between the Kinect based system and the Cortex system. As shown in Figure 9, the discrepancy can be as large as 0.2 meters when the subject's fingers are reaching for the toe. This large measurement error in the Kinect system apparently will not prevent us from using Kinect to assess rule 2.

We can assess rule 3 by measuring the displacement of the ankles with respect to their initial positions. If the ankles do not move, the

Figure 8. A comparison of the knee angles for toe touch

Figure 9. A comparison of the distances between the two shoulder joints with respect to their initial positions for toe touch

displacement should be close to 0. As can be seen from the Cortex system data shown in Figure 10, indeed this was the case. However, the Kinect data exhibited large displacement during toe touch, probably due to self-occlusion. This clearly shows that we cannot use Kinect to assess rule 3.

We can assess rule 4 by measuring the angle formed by the foot and a forward vector, in exactly the same way as that for hip abduction rule 6. If the feet are pointing forward, the angle should be

0. As shown in Figure 11, this was not the case as revealed by the Cortex system measurement (with an angle around 40 degrees). The angles measured by Kinect were significantly larger (about 60 degrees) and varied significantly in the presence of self-occlusion. Hence, we conclude that we cannot assess rule 4 using a Kinect based system.

In summary, only one of the four correctness rules can be assessed by a Kinect-based system for the toe touch exercise. Hence, we cannot use

Figure 10. A comparison of the ankle displacement for toe touch

Figure 11. A comparison of the foot angle for toe touch

such a system to evaluate the correctness of the toe touch exercise and provide meaningful feedback to the patients before the self-occlusion problem is addressed by the Kinect research community.

FUTURE TRENDS

The current Kinect SDK has two obvious limitations: (1) it captures only 20 joints in Kinect v1 and 26 joints in Kinect v2, and (2) the joint positions often contain large errors in the presence of occlusion. As we have shown in our feasibility study results presented in the previous section, the limitation of the joint set prevents us from monitoring subtle pelvis movement, and the large errors in joint positions in the presence of self-occlusion make it impossible for us to use Kinect to evaluate some correctness rules, especially for exercises that involve self-occlusion predominately. There have been intensive research and development efforts to address the two issues (Han et al., 2013). For example, a Kinect based motion capture system for finger tracking was designed, implemented, and thoroughly validated in a very recent work (Metcalf et al., 2013). The self-occlusion problem has been tackled by using sophisticated machine learning methods with constraints (Shen et al., 2012), by incorporating the reliability estimation

on the selection of kinematically valid postures (Shum et al., 2013), and by using multiple Kinect sensors (Asteriadis et al., 2013).

CONCLUSION

In this article, we presented our work on a validation study of using Microsoft Kinect to monitor rehabilitation exercises. Differing from other validation efforts, we focused on a system-level assessment instead of the joint-level comparison with reference motion capture systems. We assessed the feasibility of using Kinect by examining the enforceability of a set of correctness rules defined for each exercise, which are invariances of each exercise and hence independent from the coordinate system used. This method is more advantageous in that (1) it does not require coordinate system transformation between those of the reference motion capture system and of the Kinect based system, (2) it does not require an exact match of the Kinect joints and the corresponding external marker placements or derived joint centers often used in reference motion capture systems, and (3) the correctness rules and their mapping for Kinect motion data analysis developed in this study are readily implementable for a real motion monitoring system for physical therapy.

KEY TERMS AND DEFINITIONS

Floor Clipping Plane: As part of the Microsoft Kinect SDK, each skeleton frame contains a set of parameters that can be used to determine the floor plane as seen by the Kinect sensor.

Frontal Plane: Using a three-dimensional (x-y-z) coordinate system, this is the plane dividing the front and back half of the body; movement in the frontal plane is typically viewed from an anterior or posterior perspective; an example of movement in this plane is hip abduction where the lower extremity is moved out to the side of the body from the midline.

Microsoft Kinect: A sensor produced by Microsoft that is equipped with a Webcam, a depth camera, and a microphone arrays. It is designed to facilitate a natural user interface.

Natural User Interface: A natural user interface enables users to interact with a computer or game console via gestures and voice commands instead of keyboard, mouse, or game controller.

Occlusion: An occlusion occurs when a joint or more is hidden from the camera. Self-occlusion means that one body part hides another part.

Sagittal Plane: Using a three-dimensional (x-y-z) coordinate system, this is the plane dividing the left and right sides of the body; movement in the sagittal plane is typically viewed from a lateral perspective; an example of movement in this plane is shoulder flexion where the upper extremity is moved from the side to up in front of the body.

Software Development Kit (SDK): A set of libraries that offer software developers the access of a set of application programming interfaces.

Virtual Reality as Distraction Technique for Pain Management in Children and Adolescents

INTRODUCTION

The problem: uncontrolled pain during medical procedures. For many medical procedures, patients remain awake during the procedure, they feel pain during the procedure, and they remember pain and unpleasantness they experienced, long after the procedure is over. These memories for the painful experience(s) can influence the patient's attitudes towards receiving healthcare, increases avoidance of medical visits that could help prevent medical problems. For example, a child who has a very painful or anxiety provoking dental procedure is more likely to become avoidant of dentists. The consequences of avoidance can be expensive. Many dental problems that could be easily prevented or corrected early on with regular checkups (e.g, filling a cavity), become much more expensive and painful problems, as the disease progresses untreated (e.g., root canal and tooth extraction) for patients who refuse to visit the dentist. Excessive pain during medical procedures is a worldwide problem, and affects a wide range of patient populations. For example, patients

with a wide range of medical problems often get intravenous (IV) ports inserted "incanulation". Once inserted, healing medications, nutrients and fluids can be administered into the patient's bloodstream through the IV port. But the initial implantation of the IV port (e.g., sticking the IV port into the patient's arm) is often surprisingly painful. The same painful port insertion procedure is used with cancer patients, burn patients, patients being prepared for surgery, and a long list of other medical problems. And IV port placement is just one of large number of medical procedures where excessive pain is common.

Some medical procedures sound fairly painless, but patients' fears and anxiety associated with the procedures can amplify the patient's negative experience. For example, with blood draws, a fairly large percentage of people faint during blood draws, despite the short duration of the procedure.

A number of psychological influences can amplify or increase how much pain patients experience during medical procedures. High anxiety can increase sensitivity to pain. Some patients

DOI: 10.4018/978-1-5225-2255-3.ch518

must receive medical procedures repeatedly. For example, children with large severe burn injuries receive several painful medical procedures per week, often daily wound cleaning and painful physical therapy skin stretching exercises, and the most painful segments of the wound care procedures often last 25 minutes or longer. If the patient has an extremely high pain during wound care, their memory for previous painful wound care sessions can increase their subjective experience of pain during subsequent wound care procedures, and make it harder to control the patient's pain using pain medications alone. There are concerns that repeated painful medical procedures can be made worse if the patient has pre-existing psychological problems such as depression or PTSD. These conditions can reduce the effectiveness of opioid analgesics. And repeated painful medical procedures during hospitalization may increase patients' risk of developing chronic pain or chronic PTSD. There has lately been a growing realization in the medical community for the need for more effective non-pharmacologic pain control during medical procedures. Use of higher doses of pain medications may increase analgesia, but also increase undesirable medical side effects of the pain medications such as nausea, delirium, constipation, urinary retention, sleeping through meals, and interference with sleeping at night. Diversion of pain medications is another concern. On the streets of the U.S.A., addiction to opioids has become a major medical problem in itself. According to the CDC, overdose deaths involving prescription opioids have quadrupled since 1999, and set a new record high in 2014 (CDC, 2016).

Because pain has a strong psychological component, in theory, psychological interventions can be used to help counteract some of the negative psychological influences. In other words, there is growing interest in using psychological techniques to help reduce pain. Typically, psychological techniques can be used in addition to traditional pain medications, adjunctively (Stinson, Yamada, Dickson, Lamba & Stevens, 2008; Koller & Goldman, 2012). Distraction is a familiar technique. Parents frequently distract children to help get

them to stop crying (using a rattle toy). Music is widely used to help patients during dental procedures. According to a Cochrane meta-analysis, listening to music resulted in a statistically significant reduction in pain, but on average, music only reduced the amount of pain by around 5% reduction (not a clinically meaningful reduction from listening to music). A stronger distraction is needed for acute pain during medical procedures.

Recently Virtual Reality (VR) has emerged as a new unusually effective distraction technique, allowing the user to be immersed in a computer-generated environment. Patients look into virtual reality goggles that block the patient from being able to watch their wound care, and earphones and computer generated sound effects and music from VR hinder the sounds of the real environment, (Hoffman et al., 2000). The user can interact with the virtual environments using a mouse or a head-tracking.

Hoffman and Patterson and colleagues co-originated the technique of using immersive virtual reality analgesia during acute procedural pain (Hoffman, 1998; Hoffman et al, 2000). Two adolescents with severe burns used immersive virtual reality during burn wound care: staple removals. Both children reported large reductions in their pain during wound care while using immersive virtual reality, compared to when the same children played a Nintendo video game during the same wound care sessions (Hoffman et al., 2000). Several controlled studies support VR efficacy in reducing pain but most of them investigated its effects on adults, in particular during procedural pain in burn patients (Hoffman, Patterson, Magula, Carrougner, Zeltzer, Dagadakis & Sharar, 2004; Maani, Hoffman, Morrow, Maiers Gaylord, McGhee & DeSocio, 2011) and during dental procedures (Bentsen, Svensson & Wenzel, 2001; Hoffman, Garcia-Palacios, Patterson, Jensen, Furness III & Ammons, 2001; Furman, Jasinevicius, Bissada, Victoroff, Skillicorn & Buchner, 2009; Wiederhold, Gao & Wiederhold, 2014).

The aim of the chapter is to review the use of VR for pediatric and adolescent pain management and its applicability in clinical settings. Between

December 2011 and September 2015 some of the most important psychological and medical databases were consulted (PubMed, ScienceDirect and Scopus), including studies in which VR was used with children and adolescents as a distraction technique for procedural pain management. Studies with only adults or that applied VR for non-procedural pain, such as chronic pain, or during non-painful procedures were excluded. Search terms included combinations of “virtual reality”, “distraction”, “analgesia”, “pain”, “children”, “adolescents”.

BACKGROUND

Although the mechanisms by which VR reduces pain are still under investigation, according to Hoffman et al., 2006, the logic of how VR reduces pain can be explained by applying the Attention Pain Theory by Eccleston and Crombez (1999). People need attention in order to feel pain. VR is very attention demanding, leaving less attentional resources available for the brain to process incoming pain signals. As a result, patients report lower pain levels during VR, they spend less time thinking about their pain, and report higher levels of fun while in VR. The essence of immersive VR is the patients’ illusion of going inside the 3D computer generated world, as if it is a place they are visiting. This illusion of “presence” or “feeling present” in the virtual world helps make VR unusually attention grabbing and unusually effective as distraction.

Slater and Wilbur (1997) made a distinction between the *immersiveness* of the VR system (e.g., the objectively measurable field of view of the VR goggles) and *presence*, the psychological illusion of going inside the computer generated world and feeling present in the virtual world. In laboratory studies, wide field of view VR goggles were significantly more effective at reducing pain than narrower field of view goggles ($p < .05$) (Hoffman, Seibel, Richards, Furness III, Patterson & Sharar, 2006). Moreover, another laboratory study with young adults (college students) showed

that an interactive VR system was significantly more effective at reducing pain than passive VR ($p < .005$) (Wender, Hoffman, Hunner, Seibel, Patterson & Sharar, 2009). In some studies, patients with a strong illusion of going inside the computer generated world were also the patients who reported greater reduction in their pain during VR, and patients who reported a less compelling illusion of going into the virtual world reported less pain reduction during VR (Hoffman, Doctor Patterson & Carrougner, 2000; Hoffman, Sharar, Coda, Everett, Ciol, Richards & Patterson 2004). Manipulating the objective *immersiveness* of the VR system has been shown to affect the magnitude of VR analgesia in predictable ways, even though the illusion of presence was not significantly higher for the high immersion VR system than for the low tech VR system ($p > .05$) (Hoffman et al., 2006; Wender et al., 2009). In other words, in some studies, increasing the *immersiveness* of the VR system significantly reduced pain, but did not significantly increase patients’ presence ratings.

VR effects on brain activity during painful stimuli have been demonstrated by Hoffman et al. (2004) in a study with adult healthy volunteers. Pain-related brain activity was measured using fMRI. During their brain scans, healthy volunteer participants received brief thermal pain stimulations during VR and during No VR. Participants reported large reductions in pain during VR, and the fMRIs showed large reductions in pain-related brain activity during VR. In another study, Hoffman et al. (2007) used pain ratings and function magnetic resonance imaging to measure how much pain participants reported experiencing, and measured pain-related brain activity in adults undergoing thermal pain stimulation and receiving opioid analgesia and/or VR distraction. Results indicated that opioids alone significantly reduced subjective pain unpleasantness ratings and significantly reduced pain related-brain activity in the insula and thalamus; VR alone significantly reduced both worst pain and pain unpleasantness and significantly reduced pain related-brain activity in the insula, thalamus and SS2, but the lowest pain scores and largest reductions in pain

related-brain activity were obtained when subjects received both opioid and VR distraction. These results support that notion that VR should be used adjunctively, in addition to traditional pain medications.

VIRTUAL REALITY ANALGESIA FOR CHILDREN AND ADOLESCENTS

Applicability and Effectiveness in Clinical Settings

VR has been used with children and adolescents between 4-19 years, mostly with burned children during bandage/dressing changes, wound cleaning or physical therapy (Hoffman 1998; Hoffman et al., 2000; Hoffman, Patterson, Carrougher & Sharar, 2001; Das, Grimmer, Sparnon, McRae & Thomas, 2005; Chan, Chung, Wong, Lien & Yang, 2007; Sharar, Carrougher, Nakamura, Hoffman, Blough & Patterson, 2007; Van Twillert, Bremer & Faber, 2007; Hoffman, Patterson, Seibel, Soltani, Jewett-Leahy & Sharar, 2008; Schmitt, Hoffman, Blough, Patterson, Jensen, Soltani, Carrougher, Nakamura & Sharar, 2011; Kipping, Rodger, Miller & Kimble, 2012; Faber, Patterson & Bremer, 2013; Hoffman, Meyer III, Ramirez, Roberts, Seibel, Atzori, Sharar & Patterson, 2014; Jeffs, Dorman, Brown, Files, Graves, Kirk, Meredith-Neve, Sanders, White & Swearingen, 2014; Hua, Yao, Zhang & Chen, 2014). Others evaluated VR analgesia for cancer with children undergoing venipuncture, lumbar puncture or port access (Sander Wint, Eshelman, Steele & Guzzetta, 2002; Gershon, Zimand, Lemos, Rothbaum & Hodges, 2003; Gershon, Zimand, Pickering, Rothbaum & Hodges, 2004; Wolitzky, Fivush, Zimand, Hodges & Rothbaum, 2005). Other studies evaluated VR effectiveness with a cerebral palsy patient during physical therapy (Steele, Grimmer, Thomas, Mulley, Fulton & Hoffman, 2003), with patients undergoing fluoride therapy and primary mandibular molar restoration (Aminabadi, Erfanparast, Sohrabi, Oskouei & Naghili, 2012) and with patients with

unknown disease during intravenous placement (Gold, Kim, Kant, Joseph & Rizzo, 2006).

VR reduced pain more than an interactive video game distraction during dressing change in a 16-years boy and in a 17-years boy (Hoffman et al., 2000), and during port access placement in a 8-years child (Gershon et al; 2003). In a pilot study, Gershon et al. (2004) randomly assigned children undergoing subcutaneous port access to three groups: VR distraction, PC screen-based distraction and no distraction. Nurses rated children in the VR and PC condition as experiencing less pain than those in control condition ($p < .05$), but no differences emerged from children reports. Similar results emerged from a study on burn children (Kipping et al., 2012).

Hua et al. (2015) found that children, their caregivers and nurse involved in the wound care reported significantly less pain levels during the dressing change in VR group compared to the standard distraction group ($p < .05$). In a randomized controlled trial study, Van Twillert et al. (2007) demonstrated that children undergoing dressing change reported significantly less pain during VR than during other forms of distraction ($p < .01$). Van Twillert et al., (2007) found that VR was somewhat superior to TV, but was not significantly more effective than watching TV.

Jeffs et al. (2014) reported that participants in the VR group reported significantly less procedural pain during VR compared to the passive distraction group (watching a movie on TV) and burn patients reported less procedural pain compared with standard care group ($p < .05$).

Seven studies also revealed significant differences between pain in the VR condition compared to a no distraction condition (Das et al., 2005; Wolitzky et al., 2005; Sharar et al., 2007; Hoffman et al., 2008; Schmitt et al., 2011; Aminabadi et al., 2012; Hoffman et al., 2014). VR continued to be effective when used for multiple treatments (Hoffman et al., 2001; Faber et al., 2013). Using relatively narrow (40 degree field of view) VR goggles, and a small sample size (ten children per group = 20 patients total), Gold et al. (2006) did not find a significant difference in pain reduction

between VR and control condition, but Gold et al.'s patients receiving VR distraction during intravenous placement were significantly more satisfied with their pain management than children in the control condition ($p < .01$). Steele et al. (2003) used VR with a 16-year-old patient with cerebral palsy undergoing physiotherapy: he reported that his pain was lower during adjunctive VR distraction than pharmacological analgesia alone.

VR Systems

The most frequently used software was "SnowWorld" an interactive virtual environment where the patients glide slowly through a 3D icy canyon and shoot snowballs at snowmen, igloos, penguins, woolly mammoths and flying fish. SnowWorld was specifically designed for burn procedural pain management and it was used also by adults in several studies about VR pain management (see reviews by Malloy & Milling, 2010; Li, Montaña, Chen & Gold, 2011). "The ice-cream factory" game, is another VR software created for children burn pain management, where subjects goal was to scare a fox away the factory by shooting it with ice-cream (Chan et al., 2007). Helmets and VR goggles used in studies varied in quality and in some cases the field of view was not mentioned in the publications.

SOLUTIONS AND RECOMMENDATIONS

On the basis of the evidence reported in the literature, VR analgesia appears to be effective for children and adolescents without side effects during dressing changes, physical therapy, lumbar puncture and port access placement. The most important medical contraindications for the use of VR regard the localization of the wound, if this doesn't allow the patient to wear the helmet, and a diagnosis of epilepsy, because the use of VR could expose children to possible epileptic seizure. These contraindications are the same as those found in

adult patients (Maani et al., 2011). In pediatric burn patients, adjunctive VR reduced pain more than a Video Game distraction. VR reduced pain more than watching an age-appropriate movie, more than other distraction techniques and adjunctive VR consistently reduced pain compared to standard pharmacological analgesia. However, we must consider that in four of these studies included both children and adults, the mean age of the sample was more than 19 and the generalizability of those results to children should be interpreted cautiously for those four studies (Hoffman et al., 2001; Van Twillert et al., 2007; Hoffman et al., 2008; Faber et al., 2013). Results exploring the use of VR with cancer patients indicate a significant VR analgesic effect during port access and a non-significant pain reduction during lumbar puncture. The lumbar puncture study (Sander Wint et al., 2002) was an early study using a passive, non-interactive VR system. Patients watched videos in a pair of low resolution VR glasses (virtual i-o glasses). VR effectiveness was likely limited by the lack of interactivity, and the narrow field of view. As mentioned earlier, Wender et al, 2009 showed that VR was significantly more effective at reducing pain when participants could actively interact with the virtual world, and Hoffman, Seibel et al (2006) showed that VR was significantly more effective at reducing pain when a wide field of view VR goggles were used (compared to narrow field of view goggles, such as those used by Sander Wint et al., 2002). Future studies using more immersive VR systems (e.g., with wide field of view VR goggles and that allow patients to actively interact with the virtual world) may get stronger results during lumbar punctures.

Because most studies didn't report helmet quality, a complete analysis on the role of this aspect wasn't possible. However, five of the six clinical studies reporting a significant pain reduction in VR condition compared to control condition, used helmet with a diagonal field of view of 50-80 degrees field of view (Hoffman et al., 2000; Hoffman et al., 2001; Sharar et al., 2007; Hoffman et al., 2008; Schmitt et al., 2011). Hua

et al, 2014 used a 40 degree FOV helmet. In two others, the helmet quality was unknown (Das et al., 2005; Aminabadi et al., 2012).

Hoffman et al. (2008) reported that pain levels were significantly lower when presence scores were higher. In contrast, Sharar et al, (2007), evaluating the differences in pain perception between adults and children/adolescents, indicated that, although children report higher levels of presence and realism than adults, there was no difference in pain reduction between the pediatric and adult age groups.

FUTURE RESEARCH DIRECTIONS

Until recently, the cost of a wide field of view VR system was tens of thousands of dollars more expensive than the narrow field of view VR goggles. In 2016/2017, the cost of a wide field of view VR system with approximately 90-110 degrees diagonal field of view, and very high resolution dropped in price from \$35,600 (not including head tracking) to approximately \$800 for one pair of wide field of view VR goggles. The \$800 helmet already includes head tracking as well as position tracked hand control input devices. There aren't any studies that describe the lifespan of a VR system, however, on the basis of our experience we can affirm that it can be considered a good investment: VR requires very low maintenance costs (mainly battery charging and cleaning gel) and, changing the VR software, it is possible to get a different VR environment and so a new distraction instrument. Moreover, most VR goggles can be adjusted on the base of inter-ocular distance and head dimensions, and it is suitable for children, adolescents and adults too.

Hoffman and colleagues recently developed a portable water-friendly VR system with a robot-like arm goggle holder (Maani et al., 2011). The custom made robot-like arm holds the goggles near the patient's eyes, and the VR goggles do not even touch the patient. This system uses the more expensive battery powered VR goggles by

NVIS MX90 VR goggles. Researchers have also been able to use a robot-like arm goggle holder with the new Oculus Rift Developers Kit Version 2 (DK2), for a patient undergoing physical therapy skin stretching exercises, with a patient who was able to tolerate having the goggles lightly touch his face (Hoffman et al., 2014).

In the U.S.A., the National Institutes of Health (NIC) are particularly interested in research on "novel therapies for pain treatment", with a specific attention to VR as demonstrated by the dozens of the funded projects using this distraction technique (Thomas, 2014). For the future, the availability of inexpensive but highly immersive VR goggles (e.g., Hoffman et al., 2014) will increase dissemination of VR studies on pain management also in other countries, including developing countries. As indicated by Hoffman et al. (2011), there is a need of more research on pediatric population, because the large numbers of children severely burned each year, but also for other kinds of painful procedures. Moreover, the importance of VR hardware and software tailored to the needs of the patient is essential to obtain a better analgesia. Recently Bidarra et al., (2013) reported that during dental procedures the patients have to reduce their movements, and created a specific software for children to use during dental procedures (Bidarra, Gambon, Kooij, Schutjes & Tzouvara, 2013). Similarly, SnowWorld, the first VR world specifically designed for pain control in burn patients, (www.vrpain.com) is specifically designed to encourage patients to sit still during wound care (e.g., as the wound care nurse uses tweezers to remove staples from an open burn wound).

CONCLUSION

More studies exclusively conducted on children (without mixed data between children and adults) are needed to evaluate the potential of VR analgesia for helping control pediatric pain in several medical settings.

In 2017, major companies such as Facebook, HTC VIVE, Sony, Magic Leap, Microsoft and others, are investing a total of several billions of dollars into developing immersive (and also augmented) virtual reality, and are mass marketing VR systems to the general public. Highly immersive VR systems are becoming more widely available, increasing the availability of immersive VR for pain control. More research using these highly immersive VR systems is needed.

KEY TERMS AND DEFINITIONS

Attention: The cognitive process that let to select information from the environment in a specific moment.

Distraction: The action to draw of attention away from the primary task to another stimulus.

Pain: Unpleasant experience connected with an actual or potential tissue damage, or described in terms of such damage.

Presence: The subjective perception of being in a virtual environment and living a realistic experience.

Procedural Pain: An acute pain caused by medical-diagnostic procedures.

Snow World: The first virtual reality environment created for virtual reality analgesia with burn patients.

Virtual Environment: An artificial 3D world, that reproduces real objects or generates new ones, with which users can interact at different levels.

Virtual Reality Analgesia: Psychological technique based on distraction, used to reduce pain in adults and children.

INTRODUCTION

The Evolutionary Algorithms (EAs) mimic behaviour of biological entities and they are inspired from Darwinian evolution in nature. The EAs have been extensively studied and applied to several real-world engineering problems. Biogeography-based optimization (BBO) (Simon, 2008) is a recently introduced evolutionary algorithm. BBO is based on mathematical models that describe how species migrate from one island to another, how new species arise, and how species become extinct. The way the problem solution is found is analogous to nature's way of distributing species. In the BBO approach there is a way of sharing information between solutions (Simon, 2008), similar to the other evolutionary algorithms such as GAs, DE, and PSO. This feature makes BBO suitable for the same types of problems that the other algorithms are used for, namely high-dimensional data. Additionally, BBO has some unique features, which are different from those found in the other evolutionary algorithms. For example, quite different from GAs, DE and PSO, the set of the BBO's solutions is maintained from one generation to the next and is improved using the migration model, where the emigration and immigration rates are determined by the fitness of each solution. These differences can make BBO outperform other algorithms (Simon, 2008). BBO has been applied successfully to several real world engineering problems (Ashrafinia, Pareek, Naem, & Lee, 2011; Bhattacharya & Chattopadhyay, 2010; Boussaïd, Chatterjee, Siarry, & Ahmed-Nacer, 2011; S. K. Goudos et al., 2012; Jamuna & Swarup, 2011; Kankanala, Srivastava, Srivas-

tava, & Schulz; Mandal, Bhattacharya, Tudu, & Chakraborty, 2011; Rathi, Agarwal, Sharma, & Jain, 2011; Silva, dos S Coelho, & Freire, 2010).

The purpose of this chapter is to briefly describe the BBO algorithm and present its application to antenna and wireless communications design problems. This chapter presents results from design cases that include patch antenna, linear antenna array, and a Partial Transmit Sequence (PTS) scheme for OFDM signals based on BBO. The chapter is supported with an adequate number of references. This chapter is subdivided into five sections. The "Background" Section presents the issues, problems, and trends with BBO. Then we briefly present the main BBO algorithm. In the next Section, we describe the design cases and present the numerical results. An outline of future research directions is provided in the following Section while in the "Conclusion" Section we conclude the chapter and discuss the advantages of using a BBO-based approach in the design and optimization of wireless systems and antennas. Finally, an "Additional Reading Section" gives a list of readings to provide the interested reader with useful sources in the field.

BACKGROUND

The mathematical models of Biogeography are based on the work of Robert MacArthur and Edward Wilson in the early 1960s. Using this model, they have been able to predict the number of species in a habitat. The habitat is an area that is geographically isolated from other habitats. The geographical areas that are well suited as

residences for biological species are said to have a high habitat suitability index (HSI). Therefore, every habitat is characterized by the HSI which depends on factors like rainfall, diversity of vegetation, diversity of topographic features, land area, and temperature. Each of the features that characterize habitability is known as suitability index variables (SIV). The SIVs are the independent variables while HSI is the dependent variable.

Similar to the other evolutionary algorithms (EAs) such as Genetic Algorithms (GAs), Particle Swarm Optimization (PSO), Artificial Bee Colony (ABC) optimization, in the BBO approach there is a way of sharing information between solutions (Simon, 2008). This feature makes BBO suitable for the same types of problems that the other algorithms are used for, namely high-dimensional data. Additionally, BBO has some unique features that are different from those found in the other evolutionary algorithms. For example, quite different from GAs, Ant Colony Optimization (ACO) and PSO, from one generation to the next the set of the BBO's solutions is maintained and improved using the migration model, where the emigration and immigration rates are determined by the fitness of each solution. BBO differs from PSO in the fact that PSO solutions do not change directly; the velocities change. The BBO solutions share directly their attributes using the migration models. The migration operator provides BBO with a good exploitation ability. These differences can make BBO outperform other algorithms (Ma, 2010; Ma, Simon, Fei, & Chen, 2013; Simon, 2008). It must be pointed out if PSO or ABC are constrained to discrete space then the next generation will not necessarily be discrete (Ma, et al., 2013). However, this is not true for BBO; if BBO is constrained to a discrete space then the next generation will also be discrete to the same space. As the authors in (Ma, et al., 2013) suggest this indicates that BBO could perform better than other EAs on combinatorial optimization problems, which makes BBO suitable for application to the PTS problem. The main computational cost of EAs is in the evaluation of the objective function. The BBO mechanism is

simple, like that of PSO and ABC. Therefore, for most problems, the computational cost of BBO and other EAs will be the same since it will be dominated by objective function evaluation (Ma, 2010). More details about the BBO algorithm can be found in (Ma, et al., 2013; Simon, 2008).

BIOGEOGRAPHY-BASED OPTIMIZATION ALGORITHM

Therefore, a solution to a D-dimensional problem can be represented as a vector of SIV variables:

$$[SIV_1, SIV_2, \dots, SIV_D]$$

which is a habitat or island. The value of HSI of a habitat is the value of the objective function that corresponds to that solution and it is found by:

$$HSI = F(\text{habitat}) = F(SIV_1, SIV_2, \dots, SIV_D)$$

Habitats with a high HSI are good solutions of the objective function, while poor solutions are those habitats with a low HSI. The habitats with high HSI are those that have large population and high emigration rate μ . For these habitats, the immigration rate λ is low. The immigration and emigration rates are functions of the rank of the given candidate solution. The rank of the given candidate solution represents the number of species in a habitat. These are given by:

$$\mu_k = E \left(\frac{k}{S_{\max}} \right), \lambda_k = I \left(1 - \frac{k}{S_{\max}} \right)$$

here I is the maximum possible immigration rate, E is the maximum possible emigration rate, k is the rank of the given candidate solution, and $S_{\max}$ is the maximum number of species (e.g. population size). The rank of the given candidate solution or the number of species is obtained by sorting

the solutions from most fit to least fit, according to the HSI value (e.g. fitness). That is the best candidate solution has a rank of $S_{\max}$ and the worst candidate solution has a rank of one. BBO uses both mutation and migration operators. The application of these operators to each SIV in each solution is decided probabilistically. In each generation, there is a probability $P_{\text{mod}} \in [0, 1]$ that each candidate solution will be modified by migration. P_{mod} is a user-defined parameter that is typically set to a value close to one, and is analogous to crossover probability in GAs. That is the migration operator in each generation is applied only if P_{mod} is greater than a random number generated from a uniform distribution from the interval $[0,1]$.

The migration for NP habitats can be described in Algorithm 1.

The X_i in Algorithm 1 is habitat i . The information sharing between habitats is accomplished

using the immigration and emigration rate. The λ_i is proportional to the probability that SIVs from neighboring habitats will migrate into habitat X_i . The μ_i is proportional to the probability that SIVs from habitat X_i will migrate into neighboring habitats.

The mutation rate m of a solution S is defined to be inversely proportional to the solution probability and it is given by:

$$m_s = m_{\max} \left(\frac{1 - P_s}{P_{\max}} \right)$$

where P_s is the probability that a habitat contains S species (e.g. the rank of the solution is S), $P_{\max}$ is the maximum P_s value over all $s \in [1, S_{\max}]$, and $m_{\max}$ is a user-defined parameter.

Mutation can be described using Algorithm 2.

The m_i in Algorithm 2 is the mutation rate of solution i . As with other evolutionary algorithms, BBO also incorporates elitism. This is implemented with a user-selected elitism parameter p . This means that the p best solutions remain from one generation to the other.

Algorithm 1. Habitat migration

1: for $i=1$ to NP
2: Select X_i with probability based on λ_i
3: if $rnd(0,1) < \lambda_i$ then
4: for $j=1$ to NP
5: Select X_j with probability based on μ_j
6: if $rnd(0,1) < \mu_j$ then
7: Randomly select a SIV σ from X_j
8: Replace a random SIV in X_i with σ
9: end if
10: end for
11: end if
12: end for

Algorithm 2. Habitat mutation

1: for $i=1$ to NP
2: Compute the probability P_i
3: Select SIV $X_i(j)$ with probability based on P_i
4: if $rnd(0,1) < m_i$ then
5: Replace $X_i(j)$ with a randomly generated SIV
6: end if
7: end for

APPLICATIONS, RESULTS, AND DISCUSSION

In this Section, we provide representative wireless communications design problems that are solved with the BBO algorithm. First, we present an example case of linear array synthesis by reducing the number elements required. The second example is that of an arbitrary-shaped patch antenna which can be used for satellite communications. The third example uses the BBO algorithm for addressing a common problem in wireless communication system, the reduction of peak to average power ratio (PAPR) of transmitted signals.

Reducing the Number of Elements in Linear Arrays using BBO

Several applications of modern wireless communications systems require radiation characteristics such as higher directivity that cannot be achieved by using a single antenna. The use of antenna arrays is the obvious solution for such a case. Among others, antenna arrays are employed for several radar and wireless communications applications in space and on earth. Their advantages include the possibility of fast scanning and precise control of the radiation pattern.

Synthesis of linear antenna arrays has been extensively studied in the last decades using several analytical or stochastic methods. The linear array design problem is multimodal and therefore requires the use of an optimization method that does not easily get trapped in local minima. The reduction of array elements plays an important role in cases where the cost, weight and size of antennas are limited. Therefore, a common goal in array synthesis is the generation of a desired pattern using the minimum number of elements. Additional constraints could include the minimum and maximum distance between two adjacent elements.

We assume a $2N$ -element linear array, which is symmetrically placed along the x -axis, see Figure 1.

Figure 1. Geometry of the antenna array

We examine the synthesis of a pattern taken from the literature. We assume that $d_{\min} = 0.5\lambda$, and $d_{\max} = \lambda$, where $d_{\min}$, $d_{\max}$ is the minimum and maximum distance between two adjacent elements respectively.

The desired pattern in this case is that of a 20-element Chebyshev array uniformly spaced with $d = 0.5\lambda$, $SLL_d = -30$ dB, and $BW_d = 17.2^\circ$. The authors in (Yanhui, Zaiping, & Qing Huo, 2008) use a non-iterative synthesis method which is based on the matrix pencil method (MPM) (S. Yang, Y. Liu, & Liu, 2009; Yanhui, Qing Huo, & Zaiping, 2010; Yanhui, et al., 2008). We set the habitat modification probability, P_{mod} , to 1 and the maximum mutation rate, m_{max} , equal to 0.001. The maximum immigration rate I, and the maximum emigration rate E are both set both to one. The elitism parameter p is set to two. The population size and the number of generations is set to 100 and 2000 respectively. We run the algorithm for two cases with 12 and 14 elements respectively. Table 1 shows the radiation pattern characteristics. We notice that our results have improved the mean square error (MSE) compared with the results from (Yanhui, et al., 2008). Both patterns achieve the desired mainlobe beamwidth of 17.2° . The first pattern with $N=12$ slightly deviates from the desired with a sidelobe level (SLL) at -29.04 dB. The second synthesized pattern with $N=14$ matches closely the desired with $SLL = -29.98$ dB. The best reconstructed patterns are shown in Figure 2 and are compared with the example of (Yanhui, et al., 2008). This figure shows that the

Figure 2. Synthesis of a 20-element Chebyshev pattern with SLL=-30dB with $N=12$ and $N=14$ elements using BBO

performance difference between the BBO reconstructed patterns with $N=12$ and $N=14$ is due to the difference at angles greater than about 75 degrees. In order to achieve lower MSE values, two more elements are required.

Arbitrary-Shaped Dual Band Patch-Antenna Design using the BBO Algorithm

The use of microstrip patch antennas in wireless communication systems provides several advantages like low profile, low cost, and ease of fabrication. Patch antennas or arrays of such

antennas in the Ku-band have practical applications in radars (Bilgic & Yegin, 2014), and satellite communications (Huayan et al., 2014; Sharma, Yadav, Kumar, Ranga, & Bhatnagar, 2011; Zhang, Mahe, & Razban, 2014).

The next design case is that of arbitrary-shaped dual band patch antenna. Figure 3 shows the patch geometry. It consists of a 5X5 grid where the blue indicates the existence of metal and the white indicates dielectric. The grid is numbered from 1 to 25 as it is shown in the figure. The patch antenna is fabricated on a dielectric substrate with $\epsilon_r = 3.38$ and 30mils thick. A coaxial feed is used, which is placed in the patch center. There-

Table 1. Comparative radiation pattern characteristics for the 20-element array design case

	Desired	MPM (Yanhui, et al., 2008) N=12	BBO N=12	BBO N=14
SLL (dB)	-30.00	-29.05	-29.04	-29.98
BW (deg)	17.20	17.20	17.20	17.20
MSE	—	7.907e-6	5.743e-6	1.299e-6

Figure 3. Arbitrary-shaped patch geometry. The blue boxes indicate presence of metal.

fore, the center grid 13 is always metal. The design goal is to minimize the S11 magnitude in two frequencies 12GHz and 14GHz. For this case, the population size is set to 10 vectors and the maximum number of iterations is set to 200. We run the BBO algorithm for 20 independent trials. The surface current distributions for the best-obtained design and the geometry are shown in Figure 4. Figure 5 presents the frequency response of the best designs. The BBO obtained antenna has a

bandwidth between 11.83 and 12.10 GHz and from 13.82GHz to 14.13GHz with $|S_{11}| < -10dB$.

A PTS Technique Based on BBO for PAPR Reduction of OFDM Signals

Orthogonal frequency division multiplexing (OFDM) is widely used in several high-bit-rate digital communication systems such as Digital Audio Broadcasting (DAB), Digital Video broadcasting (DVB) and wireless local area networks (Hara & Prasad, 1997; Van Nee & Prasad, 2000). OFDM systems still have several research challenging issues. A major drawback of OFDM signals is the high value of peak to average power ratio (PAPR). Thus, it is important to reduce the PAPR of OFDM signal in order to fully utilize the OFDM technical features. Partial transmit sequences (PTS) (Cimini Jr & Sollenberger, 2000), is a popular PAPR reduction method with good PAPR reduction performance. However, PTS requires an exhaustive search in order to find the optimal phase factors. Thus, the search complexity is high. Several methods have been published in the literature for PAPR reduction using PTS with low search complexity.

In an OFDM system, the high-rate data stream is split into N low-rate data streams that are si-

Figure 4. Simulated surface current distribution of the best design found by BBO (a) at 12 GHz, (b) at 14 GHz

Figure 5. Simulated S11 curve for the best design found by BBO

multaneously transmitted using N subcarriers. The discrete-time signal of such a system is given by:

$$s_k = \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} S_n e^{\frac{j2\pi nk}{LN}} \quad k = 0, 1, \dots, LN - 1$$

where L is the oversampling factor, $S = [S_0, S_1, \dots, S_{N-1}]^T$ is the input signal block. Each symbol is modulated by either phase-shift keying (PSK) or quadrature amplitude modulation (QAM).

In the PTS approach the S input data OFDM block is partitioned into M disjoint subblocks represented by the vector S_m $m = 1, 2, \dots, M - 1$ and oversampled by inserting $(L - 1)N$ zeros. Next, the subblocks are converted to time domain using LN point inverse fast fourier transform (IFFT). The PTS objective is to produce a weighted combination of the M subblocks using $b = [b_1, b_2, \dots, b_M]^T$ complex phase factors to minimize PAPR. In order to reduce the search complexity the phase factor possible values are limited to a finite set. The set of allowable phase factors is:

$$A = \left\{ e^{\frac{j2\pi n}{W}} \mid n = 0, 1, \dots, W - 1 \right\}$$

where W is the number of allowed phase factors. Therefore in case of M subblocks and W phase factors the total number of possible combinations is W^M . In order to reduce the search complexity we usually set fixed one phase factor.

The block diagram of the PTS technique is shown in Figure 6.

The optimization goal of the PTS scheme is to find the optimum phase combination for minimum PAPR. Thus, the objective function can be expressed as:

$$\text{Minimize: } F(b) = 10 \log_{10} \frac{\max_{0 \leq k \leq LN-1} |s'(b)|^2}{E[|s'(b)|^2]}$$

subject to:

$$b \in \left\{ e^{j\phi_m} \right\}^M \text{ where } \phi_m \in \left\{ \frac{2\pi l}{W} \mid l = 0, 1, \dots, W - 1 \right\}$$

Figure 6. Block diagram of the PTS technique

We have evaluated the objective function above using different evolutionary algorithms and methods found in the literature. We have used two main measurement criteria namely the complementary cumulative distribution function (CCDF) and the computational complexity. In all our simulations, 10E5 random OFDM blocks are generated. The transmitted signal is oversampled by a factor $L=4$. We consider 16-QAM modulation with $N=256$ sub-carriers which are divided into $M=16$ random subblocks. The phase factors for $W=2$ are selected. We consider the first phase factor to be fixed so the total number of unknown phase factors is $M-1$. Figures 7a and 7b show the comparison between the CCDF by BBO-PTS and other PTS reduction techniques. For $\Pr(PAPR > PAPR_0) = 10^{-3}$ the PAPR of the original OFDM transmitted signal is 10.84dB. For all evolutionary algorithms, the population size NP is set to 30 and the maximum number of generations G is set to 30. Thus, the computational complexity of BBO-PTS for this case is $NP \times G = 900$. The PAPR by the BBO-PTS is 6.32dB. The computational complexity of the exhaustive search is $W^{M-1} = 32768$ while the PAPR for this case is 5.86dB. The PAPR by the iterative

flipping algorithm for PTS (IPTS) (Cimini Jr & Sollenberger, 2000) is 7.55dB with search complexity $(M-1)W=30$. The PAPR by the gradient descent method (GD) (Han & Lee, 2004) with search complexity $C_{M-1}^r W^r I = C_{15}^2 2^2 3 = 1260$ is 6.96dB. We also use the Random Search (RS) (Cimini Jr & Sollenberger, 2000) method by selecting 900 random phase factors. The PAPR for this case is 6.37dB. The PAPR by Artificial Bee Colony (ABC) PTS (Y. Wang, Chen, & Tellambura, 2010), Particle Swarm Optimization (PSO) PTS (Wen, Lee, Huang, & Hung, 2008), and Ant Colony Optimization (ACO) PTS (Dorigo & Stutzle, 2004), is 7.01dB, 7.13dB, and 6.52dB, respectively.

FUTURE RESEARCH DIRECTIONS

The research domain of biogeography-based optimization is growing rapidly. Several extensions of the original algorithm have been emerged. Among others a trend in BBO research is to use different migration models like curve shapes (Ma & Simon, 2011a), and blended migration (Ma & Simon, 2011b). A performance comparison

Figure 7. a) PARP reduction performance comparison of BBO-PTS algorithm with other PTS schemes for $NP=30$, $G=30$. b) Zoom in view of PARP reduction performance comparison of BBO-PTS.

of different migration models is given in (Guo, Wang, & Wu, 2014) and in (Ma, 2010). Other BBO variants proposed include (Ma & Simon, 2011a), blended migration (Ma & Simon, 2011b), oppositional BBO (Roy & Mandal, 2011), real-coded BBO (Gong, Cai, Ling, & Li, 2010), chaotic BBO (Saremi, Mirjalili, & Lewis, 2014), and BBO with a polyphyletic migration operator (Xiong, Shi, & Duan, 2014).

BBO hybrids with other algorithms is also a growing research trend. BBO has been combined with Differential Evolution (DE) (Gong, Cai, & Ling, 2011), with evolutionary strategies (Du, Simon, & Ergezer, 2009), with Harmony Search (HS) algorithm (G. Wang et al., 2013), and local search methods (Feng et al., 2013). The application of multi-objective BBO algorithms (Costa E Silva, Coelho, & Lebensztajn, 2012; Jamuna

& Swarup, 2012; Li & Yin, 2013) to antenna and wireless design problems introduces new challenges regarding performance and computational cost. Recently a novel Multi-objective BBO algorithm has been applied to wireless networks design (Sotirios K. Goudos, Plets, Liu, Martens, & Joseph, 2015). Therefore, new research directions have to be explored.

CONCLUSION

In this chapter, we discussed and evaluated the application of BBO optimizers to antenna and wireless communications design problems. BBO is a recently introduced global stochastic optimizer that is based on mathematical models of species migration. Our results show the efficiency of this approach for antenna synthesis. In the design case presented here, the BBO results are better than those found in the literature. The BBO algorithm has been applied to the design of an arbitrary-shaped patch antenna. The obtained best design is quite efficient in both frequencies. Additionally, we have used BBO a new low complexity PTS scheme. The comparison with other existing PTS reduction methods shows that BBO-PTS performs better than other methods with the same computational complexity. Simulation results show that BBO-PTS is an efficient and powerful tool for PAPR reduction of OFDM signals.

Recent BBO algorithms and their application to wireless communications problems will be part of our future work. The BBO algorithms can be valuable tools for constrained single or multi-objective optimization problems in antennas and wireless communications.

KEY TERMS AND DEFINITIONS

Genetic Algorithms: A stochastic population-based global optimization technique that mimics the process of natural evolution.

Mainlobe Beamwidth: In a radio antenna's radiation pattern, the main lobe, or main beam is the lobe containing the maximum power. The beamwidth of the main lobe is the width of the main lobe specified by the angles between the points on the side of the lobe where the power has fallen to zero.

Sidelobe Level (SLL): The ratio, usually expressed in decibels (dB), of the amplitude at the peak of the main lobe to the amplitude at the peak of a side lobe.

Orthogonal Frequency-Division Multiplexing (OFDM): A method of encoding digital data on multiple carrier frequencies.

Digital Audio Broadcasting (DAB): A digital radio technology for broadcasting radio stations.

Digital Video broadcasting (DVB): A suite of internationally accepted open standards for digital television.

Wireless Local Area Network (WLAN): A network in which a mobile user can connect to a local area network (LAN) through a wireless (radio) connection. Most modern WLANs are based on IEEE 802.11 standards, marketed under the Wi-Fi brand name.

BYOD (Bring Your Own Device), Mobile Technology Providers, and Its Impacts on Business/Education and Workplace/Learning Applications

INTRODUCTION

Concepts of BYOD

Until recently, was the norm for the employee could only do company work on a company device. Technological advances are now assisting individual's access to company information and applications on personally owned devices. BYOD (i.e., bring your own device), is making significant advances in the business world with about 44% of employees already using it at work. Companies are having a hard time controlling the employees from bringing their devices into the office and believe that implementing a BYOD policy will help employees be more productive.

The concept of BYOD was introduced in 2009 and has grown rapidly in the past few years. As of 2015, 74% managers/professional workers stated that their organization is using or planning to use BYOD" and "just over a quarter of have ruled it out entirely (Hammond). According to Apple, using BYOD can boost mobile workforce. "Users connect their mobile devices to the network without assistance from IT, and get first-tier technical support through online reference documents and instructional videos" (Apple). Being able to use these mobile devices in a group setting can substantially improve work efficiency. The devices are more mobile and are easily functioned.

Another process in information systems that BYOD could be implemented with is cloud computing. When the business has a cloud server, the employees will be able to access company data and information from their mobile devices and desktop computers in the firm. Some businesses that already have BYOD are using their devices to connect to cloud services in order to save space on the firm's computers. Although cloud computing could be beneficial for the firms in terms of storage, some employees and administrators feel uneasy about cloud computing. Some of the data that needs to be stored is often confidential information about customers about the business. Allowing that information to be uploaded to the Internet and open for everyone to see could be hazardous for the firm in the long run. When employees bring their own device, they have to make sure that their devices are not jail broken or altered in anyway. This could cause data leakages within the company, which could later lead to lasting consequences. Anyone could get ahold of their information and leak data to the world. Ensuring that the firm's cloud computing is secured and protected is one of the biggest challenges in implementing it.

According to Qrunfleh, Tarafdar, & Ragu-Nathan (2012), one main cost for any firm is a lack of knowledge of supply chain integration and how to manage a company's inventory. A company

does not want to order as many products as they can and expect to sell items immediately and successfully. BYOD would allow the flexibility of all members in the supply chain to access the level of communication technology needed to develop long-term supplier integration. It is very important to understand how supplier management practices and IS strategies can help a business improve their supply chain performance. To improve supply chain performance, a business needs to adopt specific information systems that support the processes and activities of their supply chain. In order to have an effective and enhanced supply chain performance, IS that a focal firm deploys in its supply chain should support and enhance the objectives and goals of supplier management practices. IS can assist a company with inventory control and provide its suppliers with production planning, so that, the right amount of inventory is made and that not too much is in production. The alignment of these aspects can provide a company with a low-cost supply chain and can reduce its labor cost as well as inventory costs. By using certain IS application aligned with supplier practices a company can have an improved supply chain performance.

Outside the traditional business institutions, a number of academic institutions are looking to add BYOD policies. For example, some K-12 schools are supplying teachers with devices that can be an aid in learning and universities are allowing students to bring their own devices to add to the enrichment of the programs. BYOD-based technology and its applications have numerous benefits, but they can be difficult to implement. Obviously, as with any technological innovation, there will always be adoption considerations and issues (Bruner & Kumar, 2005; Burton-Jones & Hubona, 2005; Chau, 1996; Chen, Gillenson, & Sherrell, 2002). Such technological innovations usually result in lower operating costs for the business, but they often require the organization to adapt (Belmans, Mobley, Page, Uy, & Lambrette, 2012). Since there are so many constraints and situations that could inhibit the security of

the business, some businesses are hesitant to use BYOD in their business.

Growth of Mobile Devices and BYOD

Few companies have made as big of an impact on our society and more specifically world culture as Apple. It is many mobile device and applications offerings, which has significantly fueled the BYOD movement. Apple, once a company on the verge of fading into oblivion made an incredible comeback, using a combination of marketing techniques and devices unlike any of its competitors. Whether leaking information deliberately to generate a marketing campaign or creating commercials that emphasize its unique draw to the business professionals and millennials, Apple, like its competition in Microsoft and Samsung, can be considered an innovative marketing company. Many researchers believe that companies like Apple that have strategically leveraged electronic word-of-mouth (eWOM) and social media platforms to become a model of business practices over the last decade (Sinha & Thirumalai, 2011; Smith, 2012; Smith, Synowka, Clark, & Smith, 2012; Smock, Ellison, Lampe, & Wohn, 2011). Such companies as Apple have not only been turning out revolutionary products, but their marketing methods (e.g., specifically the product launches) have been brilliant. Because of this, they have had one of the fastest expanding market presences in recent memory over the last decade. Once a company that lagged far behind Microsoft in every important category, Apple has now carved out its own niche, cornering the market on hand-held electronic devices like iPods, iPhones, and iPads. The authors of this chapter firmly believe that they could be in a position to strategically leverage the BYOD movement to the next level with their product and accompanying security features to allow professionals to use sensitive corporate and customer data.

Apple excels at turning brand into market shares. When the iPod was first introduced, Apple made sure that it had its iTunes store in place. In

addition to marketing MP3 players, Apple made money from selling downloadable music. The original iTunes store sold music that could only play on iPod players, making it a proprietary marketing strategy. That basic strategy continued with the arrival of the iPhone and the iPad, which use proprietary software applications.

Once Apple succeeded in convincing buyers that the only MP3 player worth having was an iPod, it set its sights on the next innovation, the cell phone market. In order to begin the marketing campaign, rumors began surfacing online in late 2006 that Apple was planning on looking into getting into mobile phones. To make the phone as affordable as possible, the company had worked out an exclusive arrangement with AT&T so that the cost of the phone would be underwritten by the cell phone carrier. In addition, building on the concept of the iTunes store, Apple came out with an “App Store,” allowing users to download software directly onto their iPhones. As always, Apple promoted the iPhone experience as totally user friendly and unobtrusive, a definite part of the Apple marketing strategy. Apple products are aesthetically attractive and seem to have an edge that other products simply do not. This provides a customer experience created to garner customer loyalty and to build trust. Apple’s marketing strategy has always been to allow developers to profit from their creations, while retaining ultimate control in order to maintain the Apple standards. There is no reason to assume that the company can equally embrace the BYOD concept.

BACKGROUND

Growth of Mobile Devices and Apple Products

The margins for the iPods and iPhones are supposed to be in the region of 40% to 50%. However, the iPad pricing strategy was reversed. Apple has priced the iPad much below prices of competitive tablets and no other manufacturer has so far been

able to reach these prices. This means that Apple is following a penetration strategy for the iPad in contrast with the iPods and iPhones. Therefore, it is a fair question to ask how Apple can have a product that can be priced much lower than the competition. There are multiple reasons for the low price, but one of the most significant ones is relationships with components suppliers. Relationships, contracts, and future deals with major component suppliers in the technology business matter a lot. Component suppliers of high quality are few, leading to a limited manufacturing capacity for the OEMs in the marketplace. Therefore, the OEM who books the manufacturing capacity of these suppliers in advance will create shortages and barriers for other OEMs. Furthermore, the target market for technology devices is characterized by innovation, excitement and dynamism, which means that any supply disruption creating shortage of products in the retail market will have extremely adverse effects. Customers are excited by the prospect of using and owning high tech products and unavailability at any point in time can put them off.

Part of Apple’s success surely has to do with their widely publicized product launches, and good example of this is the iPad product launch. Apple launched its very first iPad campaign during the Oscars a few years ago. The campaign was centered on one key video asset: Meet iPad. Besides being the first ad campaign for the iPad, the campaign was special for another reason as it marked a shift in Apple’s video advertising strategy. Prior to this iPad spot, Apple had been trying to drive traffic to Apple.com. Meet iPad was the first ad campaign that Apple actively pushed in video by publishing it to YouTube. The campaign was a hit. It drove over 2.5 million views in a week and inspired over 100 video placements uploaded by audiences across the web, all which contributed to views for the campaign. This pair of videos, the typical 30-second TV ad and a long form featurette, has become standard practice for Apple with its product announcements. Both go onto Apple’s YouTube page almost immediately

after the product event. Apple has made it standard practice to run paid media on YouTube for the new assets. The paid media component of these video campaigns makes them predictable. This strategy of launching an ad alongside a long form featurette goes back to the iPad 2 launch, which drove over half the views for its introducing iPad 2 campaigns from its featurette. iPhone 4 and iPhone 4S took this approach. The featurettes for both of these iPhone launches have driven well over 10 million views.

The iPad represented an evolution for Apple from their specialization in personal computers to their specialization in hand-held computers. Its release was preceded by the iPhone, which revolutionized the market of mobile computing with its innovative touch screen system. During 2007, the year the iPhone was released, Apple CEO Steve Jobs had announced that Apple would no longer go by the moniker Apple Computers, and instead would be called Apple, Inc. This was representative of the shift to mobile devices that Jobs envisioned for Apple. Rumors about the iPad began circulating not long after the iPhone had hit the shelves and experienced tremendous success. It would later be admitted by Jobs that the iPad actually was developed before the iPhone, but work on the iPad was stopped when he realized all of the capabilities of the tablet could be packaged into a phone. It seems very possible that Apple leaks of information contributed to the rumors swirling around the iPad. This is part of the genius of Apple's marketing ploys surrounding the iPad product launch. They developed consumer interest through rumors and speculation long before the iPad was turned out to store shelves. By the time the iPad product launch occurred, it almost seemed anticlimactic. People had been discussing the tablet for what seemed an interminable amount of time, and Apple fans were waiting for the iPad like anxious kids on Christmas morning. The iPad product launch occurred on April 3, 2010. Pre-orders had begun mid-March, and even though Apple initially only offered the iPad at The Apple Store, they sold 300,000 iPads on the first day of

the product launch. A month later, they had sold 1,000,000. By the time of the product launch for the second generation of iPads, Apple had sold 15 million of the first generation. Since then, Apple has showcased more generations of the iPad, each of which experienced similar success to the first version. The device is now fully Wi-Fi and 3G capable, and has garnered world-wide success ("What you can learn from" 2012).

It is interesting to note that they remove old ad campaigns from the Net so that you can only view the newest ones. In fact, if one goes to YouTube to search for these original assets for Apple's past products, not much will be typically found. The company may have recognized the value of launching video campaigns for new products, but this doesn't mean that they've completely bought into a world where people are in control of their media and are free to choose to watch essentially whatever they want. One of the benefits of online video for advertisers is that videos and campaigns never die. Even when paid media dries up, the video assets live on. When advertisers launch new campaigns, the old assets typically get a bump in views from being reactivated. Unless the promoters kill them, and Apple has done just that. With every new product launch, Apple is effectively killing its old campaigns, making the assets private on YouTube. At a glance, this makes sense: you don't want people getting distracted from a new product with new messaging with an old product and old messaging.

Thus, when it come it comes to product launches and driving anticipation, Apple has learned from their past mistakes and modified successful product launches to ensure even greater launches in the future. In both promotions, Apple leaked info to create interest and curiosity, and then followed up with the formal introduction on TV and the net. Both campaigns appeal to an audience that utilizes the phone and the pad for business and pleasure. Apple is consistent with the video ad approach and the TV ads although how they presented each and the target market is slightly different. Both product launches for the

iPhone and iPad have been met with eager anticipation and impressive sales figures. However, Apple has managed to uniquely craft each product launch to best penetrate the market considering the circumstances in front of each new launch. The challenges associated with BYOD penetration and its potential dependence on Apple products have similar characteristics to the various product launches of Apple.

CASE STUDY

Intel and its Application of BYOD

As previously discussed, BYOD is when an individual brings their personally owned device into the workplace or classroom. These devices include iPhones, iPads, tablets and laptops. BYOD first started when Intel recognized an increase in employee devices being brought to work and connected to the corporate network. As noted by Compeau, Haggerty, and Chandrasekhar (2013), M. Harkins, the chief information officer at Intel wanted to extract value from the initiative and turn BYOD into a new source of competitive advantage. He forecasted the number of employee devices being brought into the workplace to triple in just one year and that more than half of his workforce would use their own device to do more than half of their job.

The trend of BYOD was causing problems with the IT professionals because they were concerned with information security within the company. An organization's immediate concern was protecting the outside devices from carrying out company information. The concerns of financial and law related issues are important, as employees were purchasing their own devices and using them to do work on the road and at the office. The practice was reducing the cost of Intel's device procurement, but increasing the cost of configuring and supporting the growing number of devices. The data of the company were extremely vulnerable and every employee hired by Intel after would

be subject to bringing their own device into the workplace. By 2009, management at Intel realized that smartphones were had extreme levels of functionality and could connected to the data center through the cloud. As noted by Compeau, et al., 2013, Harkins gathered input from employees who were bringing their own devices as well as from employees who were not and 100% of employees viewed that the company should be managing the security of personal devices, allowing employees the freedom to bring their own devices to work. Hence, it was decided that management would control the devices as long as the employees accepted the training that went along with being able to bring their devices to work and other BYOD-based initiatives.

Historically, the company had a relatively small percentage of computer notebooks were lost per year that were either misplaced or stolen. However, under the recently adopted BYOD initiative, this inventory shrinkage of computer hardware was no longer a problem. Since the company no longer needed to purchase computer hardware, the BYOD policy promoted employees to become more conscious over where their devices were because of their ownership. It was found that the BYOD policy was increasing productivity and it was lessening the costs of data plans.

Probably, management did not predict that a BYOD policy was an issue of technology, but more about the underlying parts of the corporation. Management was having trouble defining a workable BYOD policy because of the various legal, human resources, and accounting issues. There were much effort to define the various details about software licensing and compliance with the BYOD policy. It was found that such policies could not cover the devices as a whole so it could only be used as a guideline or framework for the company.

The policy was set up in a level system so that each item under the umbrella of the BYOD policy would be covered. As noted by Compeau, et al., 2013, most companies have found that multi-tier IT architecture provides the most security as well as

very profitable investments. In general, companies need to protect against direct cyberattacks and Advanced Persistent Threats (APT) when developing their IS support systems. The degree of security and ROI are a function of level of access to data and services, with associated degrees of IS commitments of resources. The lowest level of security and IS commitments would be those data that are publicly available (i.e., real-time stock price movements, general corporate information available on public list serves and computer financial databases). The next level of increasing security and IS commitments would be more personal and confidential applications (i.e., payroll, health insurance, human resources information, to name a few) that directly involved personally identifiable information (PII). At this level, management must actively factor the issues of privacy, even though the device was owned by the employee. The next level security and IS commitments are basic corporate data used in decision-making and is the permissive level of access to corporate data (i.e., calendar of events/meetings, contacts, e-mails). The next level of security and IS commitments is more intermediate and more specific to the applications that employee would need to completed their assigned tasks (i.e., applications pertaining to specific lines of business). The most exclusive level of security and IS commitments (referred to as the Managed Equivalent) would have the most permissive level of access and would be the most traumatic to the company's operations if a security breach would occur.

For a short-term, as previously outlined, Intel only wanted the activity of the business to be understood by a few employees in the organization. With improved CoIT (Consumerization of IT), the company's engagement with customers, vendors, and partners improved drastically. It was easier for stakeholders to do business with the company and it was easier for new customers to sign up for the company's offerings. The two main security risks in Intel were device and data. The security risk with devices were new to

Intel because before BYOD they could control how many devices were company property. Now, the employee was responsible for his or her own device. The hardware operated by Intel was made with built-in information security features including security settings, log-on procedures, authentication protocols, access controls, firewalls, and anti-malware software. The new BYOD-based policy would compromise the devices and trying to secure both unmanaged and managed devices could potentially wipe out the entire encryption.

Ultimately, global IDs (such as Google ID and Live ID) were becoming popular and employees were trying to have multiple global ID's on the same devices they did their work. Integrating the ID and the corporate directory was creating security risks and the passwords protecting Intel's cloud was not strong enough to protect the secret corporate data. Since sharing corporate data will continue to be a major strategic issue, managers will still be reluctant in many cases to allow employees to place corporate data onto their own device and cross tied such confidential data with the employees' home computer. Such easily downloadable data files may be vulnerable to employees' family's devices and could be unknowingly shred with cybercriminals and competitors. Therefore, country-wide security issues have become increasingly important issues as managers typically are concerned with data protection laws abroad, or their lack of. In general, domestic companies have legal requirements, under the U.S. Federal Rules of Civil Procedures (FRCP), to formally follow demands from the courts of law for documents in the event of litigation, as evident with the recent Apple's case involving the FBI's investigation concerning information on a company owned device in the hands of a employee whom was also a terrorist suspect. Hence, the Apple and the U.S. Justice Department latest positions of world's largest company against the federal government on the extraction of data from an iPhone used by a gunman in the San Bernardino, CA (Benner & Lichtblumarch, 2016) certainly highlights

the difficulty that could arise from any BYOD policy and its unintended policies associated with e-Discovery.

The challenges in e-Discovery are several, as briefly outline in Apple's case with the federal government, as the matter of ownership is extremely important. The actual iPhone was owned by the company where the suspected gunman was employed and has since giving their consent for the data to be recover for homeland service purposes. If the company does not own the devices and individual employees do, therefore personal ownership precludes intervention by IT management without consent. Of course, in the case with Apple, that was not the case. In the case of Intel, with BYOD devices used by 10,000+ employees is not the similar case, it does underscore the complexities of BYOD policies. Different categories characterize such complexities [e.g., data (corporate data verses non-corporate data; device-created data, versus application-created data; user created versus data-making retrieval)] are important issues that need strict oversight to make BYOD policies work. There is the important issue of location of actual data (e.g., located on corporate network, a server, a cloud, a telecom carrier, or the employee-owned device) is critical as well when responding to an e-Discovery request.

With all of the benefits and challenges, many companies need to be very careful in any strategic initiative designed to integrate BYOD within the workforce environment. Considerations include financial planning (e.g., purchasing devices to support the loads of unmanaged devices), security (e.g., to protect the company data and response in a timely fashion to legitimate e-discovery requests) all require requiring employees to sign appropriate disclosure forms. The company still has to manage the devices brought into their offices on a daily basis. With hiring new employees and new devices being upgraded more often, the IT department is on its toes when it comes to securing the data and managing all the devices. It is a constant task to keep up with and Intel will always be a step ahead.

Institutions of Higher Learning and applications of BYOD

With technology growing and textbooks becoming more expensive, technology in the classroom is becoming more popular. Teachers are using PowerPoint presentations to present on topics in class to students and many students are using tablets and computers to do simulation exercises on the topics. Learning is becoming more and more interactive through available and shared technology. When discussing the topic of BYOD and its role in innovative teaching strategies, it is critical for a business or school to look at the various advantages and disadvantages of implementing such a policy. The obvious benefits that employers or school boards have initially attractive are the cost savings of implementing a BYOD policy. BYOD can improve the user's retention rate of information. Listening to a professor lecture about supply chain management may be a difficult proposition if only theory was represented. However, if a podcast was followed by active links to videos and current topics by Internet news services, perhaps student will be more likely to retain and understand the information due to visual aids. Each student learns differently as some students learn through listening and others learn through doing. Showing a video or doing an activity can only increase the knowledge retained, especially if each student follow an adopted BYOD policy sponsored by their institution.

Students have the potential to substantial savings on textbooks if schools implemented a BYOD policy. They could buy the less expensive versions of the textbook online via eBooks and bring a laptop and/or tablet to class. This policy may improve the student's health because they do not have to carry heavy books and backpacks that would could result in spinal or back disorders. Due to the convenience of a mobile device, as Apple products previously discussed, it may enhance learning as tablets and smartphones are easily available and do not require elaborate or heavy storage. Hence, administration at these BYOD-

Table 1. Worldwide device shipments by segment, as of December 2013 (partially adapted from “Gartner says worldwide ...” 2014)

Device Type	2013	2014	2015
PC (Desk-Based & Notebook)	299,342	277,939	268,491
Tablet (Ultramobile)	179,531	263,450	324,565
Mobile Phone	1,804,334	1,893,425	1,964,788
Other Ultramobiles (Hybrid & Clamshell)	17,195	39,636	63,835
Total	2,300,402	2,474,451	2,621,678

Note: Numbers are in 1000s of units.

sponsored schools could create their own rules and regulations regarding the students bringing their own devices. The policy would state what the devices should be used for and if seen using them in any other way than for learning purposes, the student could be asked to put it away and that could be the punishment.

An obvious challenge to the BYOD movement is the potential high risk of security breaches (e.g., APT and direct cyberattacks). Corporate and educational organizations' operated Wi-Fi networks are usually secure and can only be accessed through proper login information. This situation usually creates little problems, since each worker/student and supervisor/teacher would need their own logon credentials in order to access the secure network. In particular, it is hoped that by securing the network, it will allow for businesses/schools to block certain websites so the employees/students cannot be distracted by gaming websites or social media. It is important to review the level of the business that needs to be done within the institution that way you can see if the policy works for its various stakeholders. Although it is not the stated purpose of this chapter to extend discussion from a more technical perspective on how to solve this problem, it is a major issue to be addressed. For example, one of the reviewers of this chapter stated “I see a big problems that our students at sport faculties are obsessed with mobile sport applications. They are analyzing sport activities of each other during the lectures and comment on their activities, etc.” Rauter, Doupona, and Fisher

(2000) suggested that mobile devices, coupled with the popular of smart phones and watches, allow athletes to train smarter. However, Al-Shuaibi, Subramaniam, and Mohd (2014) acknowledged that mobile applications, including sports, are becoming a major distraction to students/employees as part of an electronic distraction (commonly termed cyberdeviance) that may lead to losses in productivity. According to a recent study, the worldwide tablet market is forecasted to grow 47% in 2014, in part due to lower average selling prices attracting new users (“Gartner says worldwide ...” 2014). Ownership of mobile devices are rapidly expanding, as evident from the statistics displayed in Table 1. Management and education must take steps to properly leverage these developments in a positive, non-distractive direction.

FUTURE RESEARCH DIRECTIONS

The global workforce needs to that envision being part of the global economy, other than just being able to identify themselves as a small component in a social network map or a box on a bulky organizational chart. There needs to be a renewed sense of shared context, at least among team members and with the business itself, if managers are to stem the growth of “virtual distance.” As noted by Sobel-Lojeski (2015), virtual distance is a sense of psychological and emotional detachment that begins to grow little by little and unconsciously when most encounters and experiences are medi-

ated by screens on smart devices. It is frequently assumed that physical separation and/or time zone gaps are the root causes of virtual distance. Although physical distance between employees may add to the problem, there may be more subtle circumstances.

According to Sobel-Lojeski (2015), virtual distance model is made up of physical distance, operational distance, and affinity distance. Physical distance deals with geographic distance, while operational distance develops when there is a general lack of shared context (resulting in white or backboard noise like miscommunications or technical problems). Lastly, with affinity distance, it becomes more subtle divisions in the workplace that can prevent deeper relationships from occurring. These disruptions in the human moments that result in avoiding richer, longer-lasting relationships or meaningful mutuality may prevent the proper motivation within the work environment that would provide happier, more productive workers. It is the hope by the authors of this chapter that promoting appropriate BYOD-based policies should reduce virtual distance by allowing students/workers to have greater flexibility and voice in their learning/working environments.

CONCLUSION

BYOD is a phenomenon that is spreading across companies and education institutions in the global economy. BYOD can create valuable strategic opportunities and creation. If done properly, BYOD-based policies can operate on a secure data infrastructure and help motivate employees as well as students by reducing virtual distance and promoting more autonomous learning/working environments. Ultimately, such policies, it is hoped, would allow for individuals to work more independently and innovatively.

KEY TERMS AND DEFINITIONS

Advanced Persistent Threats (APT): Advanced Persistent Threats typically employs a number of phases and techniques to break into a network, avoid detection, and gather customers' or companies' information over an extended time period. Unfortunately, such well-planned and extensive strategy is difficult to detect, as it many

techniques and phases may be extremely complex and expensive to develop a counteroffensive that is successful.

BYOD: Types of AIDC-related technologies to leave the human element out of the data collection and storage functions of information derived from manufacturing, integrated through the manufacturing process, types of authentication concerns and/or e-security strategies, and relationship links to customer profiles. Typical types of AIDC include, bar-coding, RFID, magnetic strips, touch memory, and smart cards.

CoIT (Consumerization of IT): CoIT refers to the strategic use of IT systems in order for a company to enhance its engagement with customers, vendors, and partners. Mutually beneficial relationships are the targets, with enhanced customer service and firms' increased profitability.

Cyberdeviance: Cyberdeviance refers to an employee's use of the company's Internet access during work hours for non-work related purposes, and is a subset of counterproductive work behavior. Counterproductive work behavior refers to any activity of an employee with the intended or unintended consequence of harm to the organization.

Direct Cyberattack: Direct cyberattack causes data communications interception at the hands of a specific hacker who may have located a specific person or Wi-Fi area in order to perform such cybercrime. A type of direct attack is direct access, where the criminal gains physical access to either the computer or its network in order to compromise security by loading worms, Trojans, compromising data, etc.

e-Discovery: This term refers to all types of electronic information storage (e.g., e-mails, directories, documents, searches, etc.) that are either targets investigations in which the affected organization need to produce evidence of such transactions. In other cases, information have been mistakenly lost or deleted and managers or employees need to retrieve message-level data.

Global IDs: This term refers to identifications tied to software associated with social media platforms (e.g., Google ID and Live ID) as well as to more company-based application-wide URI that uniquely identifies a particular model. Global IDs as referred to in this chapter refers to simple identifier to reference a variety of classes of objects (i.e., payroll, operations planning, job scheduling). Global IDs typically reference a model object so that it can more easily locate a model and/or application at the time it needed to perform the specific task by employees/managers.

Personally Identifiable Information (PII): Personally identifiable information (PII) refers to all information, including personal financial and healthcare information that can be traced to an individual customer or patient.

Virtual Distance: Virtual distance is a psychological and emotional sense of detachment that may result from lack of human interactions or from the loss of the human moment. Students and employees that share cultural values, similarities in communication style, and attitudes toward work can directly mediate the effects of office isolation.

Cell Phone Conversation and Relative Crash Risk Update

Richard A. Young

Driving Safety Consulting, LLC, USA

INTRODUCTION

A few brief definitions of basic terms will facilitate understanding the research updates reviewed in this chapter. This chapter uses the same definitions of terms as in the corresponding article in Chapter 102 in the previous edition of this Encyclopedia (Young, 2015a), except for the following additions and enhancements.

- **Confidence Interval:** In this paper, the 95% Confidence Interval (abbreviated CI). “If the underlying statistical model is correct and there is no bias, a CI derived from a valid analysis will, over unlimited repetitions of the study, contain the true RR with a frequency no less than 95% of the time” (Porta, 2008, p. 49).
- **Demand Terms:** The metrics characterizing driver performance during secondary tasks can be grouped into the two orthogonal dimensions of *Physical* and *Cognitive* demand (Young, 2016a, 2016b). *Physical* demand concerns the aspects of secondary tasks which place demands on the eye glances, hands, or feet of the driver. *Cognitive* demand concerns the aspects of secondary tasks that place demands upon the attentional resources of the driver.
- **Driver Distraction:** “Driver distraction is the diversion of attention away from activities critical for safe driving toward a competing activity, which may result in insufficient or no attention to activities critical for safe driving” (Regan et al., 2011, p. 1776). As pointed out by Young (2015a, Section

6), a secondary task with a relative risk confidence interval that encompasses one, or that is entirely below one, is not a driver distraction according to this definition, because the secondary task does not impair activities critical for safe driving.

- **Epidemiological Terms:** *Case window.* In naturalistic driving studies, a short time period (often 6 seconds) near the time of the precipitating event, which in turn immediately precedes the time of the crash. *Control window.* A time period with the same duration as the case window, but during driving on some day before the crash, when there was no safety-related incident. *Homogeneous.* Assume the population under study is divided into two or more categories or strata (e.g., defined by exposure and confounder levels). The homogeneous assumption is that within each analysis subgroup, “the probability (risk) of an outcome event arising within a unit of person-time is identical for all person-time units in the stratum” (Rothman et al., 2008, pp. 239-240). That is, the effect is constant or uniform across strata. If so, the strata can be pooled or combined (e.g., crashes and near-crashes can be combined into one group). If the effect is not equal across strata, then epidemiologists say that the effect measure is *heterogeneous*, meaning that it is modified or varies across strata (Rothman et al., 2008, p. 63). Strata that are heterogeneous cannot properly be pooled to create a single estimate. Standard tests for homogeneity exist in epidemiol-

DOI: 10.4018/978-1-5225-2255-3.ch521

ogy and should always be used before combining strata. *Confirmation bias* is “a form of bias that may occur when evidence that supports one’s preconception is evaluated differently from evidence that challenges those conceptions” (Porta, 2008, p. 49). *Selection bias* refers to “a distortion in the estimate of the effect due to the manner in which subjects are selected for the study” (Porta, 2008, p. 225). An example of a potential reason for selection bias is if all drivers with a safety-critical event are chosen for the exposed group, and only at-fault drivers with a safety-critical event are chosen for the unexposed group (Young, 2013a). Another example of selection bias is if drivers engaged in a cell phone conversation accompanied by other secondary tasks are chosen for the exposed group, and drivers without any secondary tasks are chosen for the unexposed group (Young, 2017a).

- **Naturalistic Driving:** An example of non-experimental driving, as is real-world driving. Vehicles are specially equipped with video cameras that record the driver’s behavior, and other instruments such as inertial sensors that record the vehicle’s behavior. These measurements occur in real time, while the vehicles are driven in everyday fashion over a prolonged period, from months to several years. A naturalistic driving study (NDS) also allows for exact timing of crashes and calls, at least those using hand-held phones. Many naturalistic driving studies do not have audio recordings, only video, so determining whether a driver is engaging in a hands-free conversation, or just singing or talking to themselves, is difficult. Hence, only hand-held cell phone conversations are evaluated in some naturalistic driving studies.
- **Real-World Driving:** Another example of non-experimental driving, as is naturalistic driving. Real-world driving refers to driv-

ing a vehicle in an everyday manner, without experimental instructions or special instrumentation. In real-world driving, tasks such as engaging in a cell phone conversation that are secondary to primary driving, if performed at all, are performed at times and under traffic and environmental conditions chosen by the driver, and no special equipment beyond that installed at the time of purchase is attached to the vehicle. Young (2001) and Young and Schreiner (2009) are examples of real-world driving studies that relied upon GPS, crash sensors, and cell phone records to determine the exact times and locations of all crashes severe enough to deploy an airbag, along with all communications using an embedded wireless device (OnStar). Studies based instead on police crash reports or crash databases are also real-world studies, but they typically have inexact crash times, making the association with cell phone conversation or other secondary tasks difficult to establish with accuracy (Young, 2014a, Appendix A).

- **Relative Risk (RR) Estimate Terms:** A *crude* RR estimate refers to a measure in which the effects of differences in composition of the populations being compared (e.g., differences in age or sex distributions) have not been minimized by statistical methods. An *adjusted* RR estimate refers to a measure in which the effects of differences in composition of the populations being compared have been minimized by statistical methods (Porta, 2008, p. 4). A *corrected* RR estimate refers to a measure that has been corrected for errors made in the analysis method, or in the underlying data. *Odds Ratio* (OR) is used in some epidemiological studies, such as a case-control study, to estimate the Relative Risk (RR). The OR estimate closely approximates the RR if the event of interest is rare (such as a crash).

- **Talk Terms:** *Talk* is used throughout this chapter as a synonym for “cell phone conversation,” meaning talking or listening on a wireless cellular device while driving. Talk Alone refers to Talk as the sole task performed in a case or control window, without another secondary task being performed in that same window. Pure Talk refers to Talk Alone without any confounding effects from driver behavior errors or driver impairments. Talk in any of these types can take place via a hand-held portable phone, a hands-free portable phone, or a hands-free wireless device embedded in the vehicle (such as the OnStar device).
- **Task Terms:** *Primary tasks* are defined as the operational tasks of driving *per se*: namely, steering, pressing and releasing the accelerator, braking, and detecting and responding with an appropriate steering or braking maneuver to objects and events in the roadway. In vehicles with manual transmissions, primary tasks would also include pressing and releasing the clutch pedal and operating the gearshift lever. *Secondary tasks* are defined as tasks performed in a vehicle by a driver that are not related to the primary driving tasks.

RECENT SCIENTIFIC KNOWLEDGE ABOUT TALK RELATIVE CRASH RISK

Study A: 100-Car NDS Talk RR Estimates

100-Car corrected crude Talk RR estimates. Klauer et al. (2006) estimated a crude Talk RR of 1.29 (CI 0.93-1.90) for the 100-Car NDS. However, their analysis method had selection bias, because all drivers with a safety-critical event were chosen for the exposed group, and only at-fault drivers with a safety-critical event were chosen for the unexposed group (Young, 2013a).

Young (2013b, 2014a) re-analyzed the original 100-Car data and corrected this selection bias by including all exposed and unexposed crash/near-crash cases (regardless of fault). The Klauer et al. (2006) crude Talk RR estimate of 1.29 (CI 0.93-1.90) was thereby reduced to 0.78 (CI 0.56-1.06). Klauer et al. (2014) later used another correct method of eliminating selection bias by including only at-fault exposed and unexposed groups, giving rise to a crude Talk RR estimate of 0.76 (CI 0.51-1.13) for experienced adult drivers in the 100-Car crash/near-crash data. The corrected crash/near-crash crude Talk RR estimate (whether 0.76 or 0.78) for the 100-Car study data is still potentially biased upward by environmental variables (e.g., traffic, closeness to junction, weather, and time of day), and demographic variables. These variables were unmatched, or only partially matched, between case and control video clips in Klauer et al. (2006, 2014).

100-Car Talk RR estimates adjusted for driver and environmental conditions. Young (2013b, 2014a) reanalyzed the 100-Car case data (VTI, 2014), the same data that had been used by Klauer et al. (2006). However, Young used the baseline data from Klauer et al. (2010) that had been matched with the environmental and driver variables to each crash/near-crash case, rather than the unmatched baseline data that had been used by Klauer et al. (2006). Young (2013b, Table 9; Young, 2014a, Table 10) found that the Talk RR estimate declined by about 23%, from 0.78 to 0.56 (CI 0.41-0.76) (Study A) by using matched baseline data. The matched baseline data removes bias resulting from the driver variables because each participant acts as his or her own control. Matching by environmental conditions also reduces bias resulting from differences between case and control video clips in variables such as traffic density, closeness to junction, weather, and time of day.

Summary: The crude hand-held Talk RR estimate from the 100-Car study, when corrected for selection bias in the analysis methods, is below one, with a confidence interval that overlaps

one. The hand-held Talk RR, when adjusted for demographic and environmental variables using matched baseline data, falls to 0.56 (CI 0.41-0.76), with a confidence interval entirely below one, indicating a protective effect.

Study B: Fitch et al. (2013) NDS Talk RR Estimates

Fitch et al. (2013) performed a matched case-control study of all *safety-critical* events, defined as crashes (including curb strikes), near-crashes, and crash-relevant conflicts. This study estimated an Odds Ratio (OR) near one for integrated hands-free Talk; i.e., 0.71 (CI 0.30-1.66). They used a method suggested by Young (personal communication) of using the driving period before the crash or near-crash in the same trip. This method matches and therefore automatically adjusts for the driver (including demographics, genetics, personality, etc.), the approximate time of day, weather, and road type. Fitch et al.'s Talk OR estimates were all near one: integrated hands-free Talk (0.71, CI 0.30-1.66), portable hand-held Talk (0.79, CI 0.43-1.44), and portable hands-free Talk (0.73, CI 0.36-1.47). These three Talk ORs for the different wireless device types were homogeneous, so they could be pooled into one estimate for Talk, regardless of device, giving rise to a tighter confidence range. The pooled RR was 0.75 (CI 0.49-1.15) (Study B).

Summary: The Fitch et al. (2013) Talk RR estimates are all below one, with a confidence interval that overlaps one, for hands-free, hand-held, and embedded cellular phones.

Studies C-E: Real-World Talk RR Estimates

Young and Schreiner's (2009) real-world cohort study of three million personal conversations on a hands-free integrated wireless device observed only 14 crashes during Talk out of 2,316 airbag-deployment crashes. The study estimated a crude

Talk RR of 0.62 (CI 0.37-1.05) (Study C), when compared to baseline driving with no Talk.

The Redelmeier and Tibshirani (1997) and McEvoy et al. (2005) real-world case-crossover studies claimed adjusted Talk RR estimates near 4.0 for crashes severe enough to cause injury. However, these studies contained a major bias by assuming that driving took place during the entire 10-minute control windows on previous days (Young, 2012a, 2013b). Based on several large GPS studies, Young (2012a, 2013b) estimated that study participants in the case-crossover studies were likely in the vehicle during only 20% of the control window periods in which they recalled driving; that is, they drove only part-time during a given control window. The number of calls made during any given time interval is lower when not in the vehicle than in the vehicle (Young, 2014a). Hence the number of calls made during the control windows was biased low, artificially increasing the estimated RRs. Correcting this bias (Young, 2014a), and also misclassification bias from counting calls made after the crash, the Redelmeier and Tibshirani (1997) Talk RR estimate reduced to 0.61 (CI 0.38-0.98) (Study D), and the McEvoy et al. (2005) estimate reduced to 0.64 (CI 0.32-1.27) (Study E), now consistent with the Young and Schreiner (2009) real-world cohort study estimate of 0.62 (CI 0.37-1.05) (Study C).

Claims that the Redelmeier and Tibshirani and McEvoy et al. case-crossover studies pooled dialling or other cell phone tasks with Talk, and that these other tasks were what elevated the RRs (rather than the bias from assuming that driving was full-time in the control windows), are invalid (Young, 2015a, Section 4; Young, 2014d), because dialling, searching for the phone to answer it, etc., do not appear in cell phone records if interrupted by a crash.

Summary: The Talk RR results of three real-world driving studies, after correction for known biases, are consistent with the naturalistic study Talk RR results in Studies A and B. Namely, the risk of crashing during a cell phone conversation

is not greater than the risk of crashing when not engaged in a cell phone conversation.

Study F: SHRP2 NDS Talk RR Estimate

Dingus et al. (2016) estimated the crude OR for hand-held Talk as 2.2 (CI 1.6-3.1), using the SHRP2 (2014) NDS dataset. This crude Talk OR estimate is high compared to those in previous naturalistic studies analyzed by the same Institute and many of the same authors: The Klauer et al. (2014) revised 100-Car crude Talk OR estimate of 0.76 (CI 0.51-1.13) (1.13), and the Fitch et al. (2013) pooled NDS dataset adjusted estimate of 0.75 (CI 0.49-1.15) (see Study B). The Dingus et al. (2016) estimate is also inconsistent with the crude 100-Car NDS Talk OR estimate of 0.56 (CI 0.41-0.76) by Young (2013b, 2014a) (see Study A).

To resolve these discrepancies, Young (2017a) directly analyzed the SHRP2 database using the Insight query program (<https://insight.shrp2nds.us/>). There were 35 Talk cases for all crashes, except curb strikes were excluded following Dingus et al. (2016). Of these, drivers in 19 cases were exposed to Talk and additional secondary tasks, and only 16 were exposed to Talk Alone. There were 240 crashes during “model driving” (where there were no secondary tasks) so the odds in favor of Talk Alone exposure among cases is 16/240 or 0.0667. There were 541 Talk Alone controls in the balanced-sample baseline without crashes. Compared to the 9,415 “model driving” controls, the odds in favor of exposure among non-cases is 541/9415 or 0.0575. The Talk Alone OR estimate is then 1.16 (CI 0.65-1.94). This Talk OR estimate further reduces to 0.92 (CI 0.29-2.2) (Study F) after eliminating confounding by driver behavior errors (Young, 2017a). This estimate is less than half the Dingus et al. (2016) OR estimate, with the confidence range now bracketing one, rather than being above one.

The upward bias in Dingus et al. arises mainly from the 19 cases that Dingus et al. included in

their exposed category, which contained additional secondary tasks in the same exposure case window as Talk. Fourteen of these cases had one additional secondary task, and five had two additional, for a total of 24 additional secondary tasks counted with Talk, even more than the 19 instances of Talk itself. These additional secondary tasks typically had high OR estimates (when analysed alone without Talk): e.g., “Cell phone, Dialing hand-held” (2.8), “Looking at an object external to vehicle” (8.7), or “Moving object in vehicle” (62.8). This result means that the Dingus Talk OR estimate was upwardly biased due to selection bias: 19 of the 35 drivers selected for the exposed group had additional secondary tasks besides Talk in their case window, but the drivers selected for the unexposed group had no secondary tasks. Removing this selection bias and the confounding bias from driver behavior errors, the corrected SHRP2 Talk OR estimate was 0.92 (CI 0.29-2.2). This SHRP2 Talk OR estimate is now consistent with the 100-Car study OR estimate of 0.56 (Study A), Fitch et al.’s (2013) matched case-control NDS pooled OR estimate of 0.75 (Study B), and the real-world study RRs reviewed in Studies C-E.

Summary: A major bias in the analysis method used by Dingus et al. (2016) arose because their exposed group contained up to 2 additional secondary tasks in the same 6-s video clips as Talk, while their unexposed group excluded any secondary task in its 6-s video clips. The SHRP2 NDS Talk OR estimate, after eliminating this and another bias, is consistent with other naturalistic and real-world studies in finding that the risk of crashing during a cell phone conversation is not greater than the risk of crashing when not engaged in a cell phone conversation, or when compared to just driving with no secondary tasks.

Confusion of Prevalence With Causality

Young (2015a, Section 9) noted a common misunderstanding in the driving safety literature; namely,

that the presence of an activity co-occurring with crashes indicates that the activity itself is a contributing factor to crash risk.

For example, Dingus et al. (2006, p. xli), based on video observations of crashes and near-crashes in the 100-Car naturalistic driving study, stated that “78 percent of the crashes had ... inattention ... as a contributing factor.” However, the 100-car data show that drivers were “inattentive” (as defined by Dingus) more than 78% of the time during baseline driving (Young, 2015c). That is, baseline driving had a higher prevalence of inattention than crashes. Hence, the Dingus et al. (2006) statement that inattention overall is a “contributing factor” risk for crashes/near-crashes is not supported by their data.

In other words, as noted by Young (2015a, Section 9), it is not valid to conclude based solely on prevalence that a distraction or other risk factor is *per se* detrimental to driving safety. To estimate whether a factor is causal, coincidental, or protective for driving safety, the prevalence (or odds, or risk) of that factor during a safety critical event must be compared with its prevalence (or odds, or risk) during control periods when there is no safety critical event.

Dingus and colleagues unfortunately carry forward this incorrect assumption about prevalence in the Dingus et al. (2016) article on the SHRP2 data. After presenting a table solely of prevalence values in their Figure 1, they state, “Other important findings from Fig. 1 show that nearly three-quarters of the crashes (i.e., 73.7%) involved some type of error; 68.3% of crashes involved some type of observable distraction; and 54.5% of crashes involved both. These findings conclusively show the detrimental impact of distraction alone and in combination with a variety of other sources of error and impairment.” Whether distraction alone or other sources of error are “detrimental” to driving safety can only be determined after a comparison to baseline driving, not simply by using prevalence numbers during crashes.

Summary: It is incorrect to make claims that an activity is a contributing factor for safety-critical

events, or detrimental to driving safety, based on prevalence alone. An appropriate comparison must be made to baseline driving before such claims can be made.

META-ANALYSIS TALK RR ESTIMATE

Table 1 and Figure 1 (end of this chapter) summarize the individual Talk RR estimates discussed in Studies A-F. The individual Talk RR estimates are homogeneous (p for homogeneity equals 0.886), so a pooled estimate can be made, which is 0.63 (CI 0.52-0.76). The pooled RR confidence interval is entirely below 1, indicating that Talk reduces relative crash risk compared to Not Talk. A likely explanation driver self-regulation as discussed in the following section.

Driver Self-Regulation

Strayer et al. (2013, 2014, 2015a, 2015b, 2015c), based on an analysis of data from their experimental studies, claim that auditory-vocal tasks (e.g. Talk, or speech interactions with in-vehicle infotainment systems) cause major driver “impairments” at “catastrophic” levels. However, Young (2014b, 2014c; 2015b) showed that the assumption by Strayer et al. (2013, 2015a) that auditory-vocal tasks (e.g. Talk, or speech interactions with in-vehicle infotainment systems) cause major driver “impairments” at “catastrophic” levels are not supported by their own data. The Strayer et al. (2013, 2015a) data, upon close examination, show instead that drivers increase their following headway to a lead vehicle during Talk, and the resultant increased headway more than offsets the small 50 to 200 ms increase in response time (RT) from the effect of Talk on orienting attention (Young, 2014b, Figure 6; 2015b). That is, drivers self-regulate their driving behavior during Talk to offset the risk increases associated with the slight increases in RT associated with the attentional effects of Talk. As a result, drivers’ overall crash

risk during Talk does not increase, and may even decrease during real-world driving (Young, 2013b; 2014a; 2014b, Figure 5; 2015b).

Specifically, Young (2014 b, 2014c; 2015b) compared the time and distance headways to the response time increases during all auditory-vocal tasks (not just Talk) in the Strayer et al. (2013, 2015a) data. He found complete compensation, in that the headway times and distances increased sufficiently such that the increases in safety margin fully offset the RT increases in all the auditory-vocal tasks in the Strayer et al. (2013, 2015a) study. The increased headways were not recognized as compensation by Strayer et al. (2013, 2015a), but were instead counted as evidence of increased impairment. However, for many tasks, the drivers increased their headways even more than necessary to offset any RT increases arising from the attentional effects of cognitive load during auditory-vocal tasks, so that there would actually be a net safety benefit to the extent that the experimental results are predictive of real-world results. These and other “overcompensations,” if substantiated in naturalistic driving studies, would help explain why the corrected and adjusted relative risks from the studies discussed in Studies A-F have ORs that are not greater than one, and the pooled relative risk estimate for Talk while driving 0.63 (CI 0.52-0.76) from the meta-analysis shown in Table 1 and Figure 1, indicating a protective effect (i.e., crash reduction).

As mentioned in Young (2015a), a useful analogy is that older drivers have slower RTs compared to younger drivers (on average, RT decreases with age). However, older drivers self-regulate by driving less often during nighttime, bad weather, and poor road-surface conditions, and by being less hurried, alcohol intoxicated, or distracted by non-driving activities (Hakamies-Blomqvist, 1994). Because of such self-regulation, older drivers fully compensate or even overcompensate for their increased RTs, and hence are the safest drivers of any age group in terms of crash rate per driver, after controlling for low mileage bias by comparing the crash rates of drivers of different

ages that were matched for yearly driving distance (Langford et al., 2006). The crash rate decreases continuously with age, even though the fatality rate for the oldest drivers approximates that of the youngest drivers, but that is because of frailty, not because of an increased crash rate.

Young (2015a) further noted that the amount of the RT increase from these attentional effects is known to depend upon the mode of the secondary task. For example, visual-manual tasks typically give rise to slightly greater RT increases (about 300 to 450 ms) than do auditory-vocal tasks (about 50 to 200 ms), compared to “just driving” with no secondary task (Angell et al., 2006; Young, 2014b, Appendix, Fig. 6). In part, this is because visual-manual tasks are typically accompanied by increased eyes-off-road time, which also increases RTs to visual events in the roadway, adding to the RT increases from the attentional effects of cognitive load associated with visual-manual tasks. However, the RT effects of the attentional component of visual-manual tasks can be measured independently of the eyes-off-road effects, because RT increases also occur when using tactile, rather than visual, Detection-Response Task (DRT) stimuli (ISO17488, 2016; Young et al., 2013d). Indeed, a two-dimensional model (with orthogonal physical demand and cognitive demand dimensions) is required to explain driver performance effects of secondary tasks (Young and Angell, 2003; Young, 2012b; 2016a, 2016b). For visual-manual secondary tasks, the physical demand component is dominant, but the cognitive demand component is non-trivial, and larger than for auditory-vocal secondary tasks, at least for the task sets examined in Young (2016b), and the Crash Avoidance Metrics Partnership task set in Angell et al. (2006) – see Young (2014b). For auditory-vocal tasks alone, without visual-manual tasks or mixed-mode tasks, the cognitive demand dimension is dominant (Young, 2016b).

Almost every experimental study of cell phones and driving behavior to date shows increases in time and distance headways associated with Talk. For example, such increased time and distance

headways during Talk are evident in eight simulator studies by Strayer and colleagues (for citations see Refs. 11-18 in Young, 2014b), as well as Brookhuis et al. (1991), Jamson et al. (2004), Ranney et al. (2004), Kircher et al. (2004), and Yannis et al. (2010).

Young (2013b, 2014a, 2014b, 2014c, 2015a) further explained why self-regulation is not always observed or reported in experimental studies. The reason is that the drivers are required to perform the tasks during the experiment in order that the physical and/or the attentional effects of cognitive demand of those tasks can be measured. Thus in an experimental study, it is not possible to measure a driver's willingness or strategy used to perform the same task under real-world conditions, when they may delay or even choose not to perform a given task until the vehicle is stopped, or they otherwise self-regulate their driving behavior when performing such secondary tasks. Such self-regulatory/compensatory driving behavior generally is more evident in direct observations of drivers of instrumented vehicles in naturalistic driving studies, although self-regulatory driving behavior can be discovered even in some experimental studies as shown in this section and in Young (2014b, 2014c). Talk also decreases the RR estimate for drowsy driving in the 100-car NDS dataset (Young, 2013c), but this result should be confirmed in the SHRP2 (2014) NDS dataset. Secondary tasks also reduce crash risk because when drivers perform secondary tasks they make fewer driver behavior errors. For example, in the SHRP2 naturalistic driving study, performing secondary tasks reduced the OR estimates for speeding by about 50% compared to not performing secondary tasks (Young, 2017b).

Summary: Driver self-regulation compensates for the effects of Talk on attention while driving, and may account in part for the overall protective effect for Talk while driving found by the meta-analysis in the previous section (see Table 1 and Figure 1).

CONCLUSION

The results from six published naturalistic and real-world driving studies of passenger vehicles to date, after correction where needed for known errors and biases, concur that the risk of crashing during a cell phone conversation is not greater than the risk of crashing when not engaged in a cell phone conversation, or when just driving with no secondary task.

A meta-analysis of these six studies finds that their relative risk estimates are homogeneous, regardless of cell phone type, crash severity, driver sample, or epidemiological study type. The pooled Talk relative risk estimate is 0.63 (CI 0.52-0.76), indicating a protective effect of cell phone conversation, which most likely arises because of driver self-regulation.

FUTURE RESEARCH DIRECTIONS

The SHRP2 naturalistic driving study offers additional data on the different subtasks of cell phone usage besides conversation: dialing, texting, locating, answering, etc. The relative risks of these subtasks should also be estimated, and the results examined for homogeneity to see if the subtasks can be properly combined into an overall estimate of the relative risk for cell phone "usage." If the tasks are heterogeneous, the various subtasks in cell phone usage must be separately reported (and legislated if needed).

There is an opportunity for future research to do a case-crossover or matched case-control study of the SHRP2 data, to adjust for driver demographic factors, as well as roadway factors, weather, closeness to junction, and so forth. In addition, illegal and improper driver behaviors (as well as other secondary tasks) that co-occur with a secondary task must be adjusted for (Young, 2017b), to arrive at unbiased estimates of the relative risks of the various cell phone usage subtasks. Finally,

research should be done to determine whether cell phone conversation reduces the relative risk of drowsy driving in the SHRP2 study data, as it did in the 100-Car study data (Young, 2013c).

ACKNOWLEDGMENT

I thank Bruce Papazian and an anonymous reviewer for comments on an early draft of this chapter.

KEY TERMS AND DEFINITIONS

Cell Phone Conversation: Talking/listening on a wireless device. Abbreviated in this chapter as Talk.

Cognitive Distraction: “Any epoch of cognitive loading that competes with activities necessary for safe driving” (Foley et al., 2013).

Cognitive Load: The loading of cognitive resources, “which are the alerting, executive, and orienting attentional networks singly or in combination, as well as the memory and representational systems (e.g., working and long-term) from which information may be retrieved and in which it may be held and operated upon” (Foley et al., 2013). Same as Cognitive demand (see Introduction).

Compensation: As used here, a synonym for self-regulation. For example, during a cell phone conversation, drivers tend to compensate for the 200-300 millisecond increase in their brake response time by increasing their headway times to a lead vehicle.

Crash Risk: The probability of crash occurrence.

Driver Distraction: “The diversion of attention away from activities critical for safe driving toward a competing activity, which may result in insufficient or no attention to activities critical for safe driving” (Regan et al., 2011, p. 1776).

Driver Attention: Attention is three entities, not one as commonly believed. The alerting, executive, and orienting attentional networks in the brain are separate networks that can be affected in opposite ways by cell phone tasks. For example, Talk improves alerting attention, while slightly diminishing orienting attention.

Relative Risk: As used in the current chapter, the crash risk of performing a secondary task

relative to the baseline risk when not performing that secondary task. Relative risk is used here as a generic term to refer to the risk ratio, the rate ratio, or the odds ratio, all of which are technical terms to estimate relative risk in different epidemiological study designs.

Secondary Task: Any task performed in a vehicle that is not related to the primary driving tasks.

Self-Regulation: A change in tactical driving behavior to compensate for adverse effects on safety from a secondary task. A synonym for compensation.

Talk RR: The relative risk of cell phone conversation while driving.

APPENDIX

Table 1. Studies discussed in main text

Study	Wireless Device	Dataset	RR Estimate	Crash Type	Study	RR	LL	UL
A	hand-held	100-Car NDS	adjusted	Crash & Near-Crash	Young (2013b, 2014a)	0.56	0.41	0.76
B	all	cell-phone NDS	adjusted	Safety-Critical	Fitch et al. (2013)	0.75	0.49	1.15
C	embedded	real-world	crude	Airbag Deployment	Young & Schreiner (2009)	0.62	0.37	1.05
D	hand-held	real-world	adjusted	Injury	Redelmeier & Tibshirani (1997)	0.61	0.38	0.98
E	hand-held	real-world	adjusted	Injury	McEvoy et al. (2005)	0.64	0.32	1.27
F	hand-held	SHRP2 NDS	crude	Moderate to Severe	Young (2017a)	0.92	0.29	2.20
A-F					pooled	0.63	0.52	0.76

Key: RR = Risk Ratio; LL = lower 95% confidence limit; UL = upper 95% confidence limit.

Figure 1. Plot of the six Talk relative risk estimates in Table 1 with confidence intervals. The pooled estimate is to the right. The pooled estimate and graph were done using Episheet (Rothman, 2015).

Comb Filters Characteristics and Current Applications

INTRODUCTION

A comb filter is a Linear Time-Invariant (LTI) *digital filter*, where linear means that its output to a *scaled* sum of input *digital signals* is equal to the scaled sum of the outputs to every one of these input signals (i.e., the filter satisfies the superposition principle) and time-invariant means that, for any input signal that has a given *delay*, the output undergoes the same delay as the input (Antoniu, 2006). The name comb is derived by the fact that its *magnitude response* resembles the teeth of a comb. Since there are several filters having magnitude responses with such characteristic, the term comb filter is rather general. The duration of the *impulse response* of comb filters can be either finite or infinite, i.e., there are Finite Impulse Response (FIR) comb filters and Infinite Impulse Response (IIR) comb filters (Zölzer, 2008).

The simplest FIR comb filter has the following *transfer function*:

$$H_a(z) = 1 + z^{-M} \quad (1)$$

This filter adds to a signal a version of that signal delayed by M sample periods, and it is the basic building block to introduce echo effects in audio signals (Zölzer, 2008). Moreover, if the addition in (1) is replaced by a subtraction, the resulting comb filter is a useful building block

to remove DC and harmonics (Diniz, Da Silva & Neto, 2010). The unintentional delay of an audio signal due to the environment is also modeled as a comb filter (Toole, Shaw, Daigle & Stinson, 2001), and this effect may be undesirable in many cases. Similarly, a simple IIR comb filter has the following transfer function:

$$H_b(z) = 1/(1 - az^{-M}) \quad (2)$$

with $a < 1$. This filter is a basic building block to model and create reverberation effects or, in general, to artificially reproduce the acoustics of a room (Zölzer, 2008).

One of the most important comb filters for several Digital Signal Processing (DSP) applications is the one based in the FIR filter where all the samples of its impulse response have values equal to one. Unlike the aforementioned comb filters described by $H_a(z)$ in (1) and $H_b(z)$ in (2), this comb filter has a low-pass characteristic, which makes it useful to pass a baseband signal and remove unwanted high-frequency spectra (Milic, 2009). The rest of this chapter is dedicated to this particular filter, which will be referred as the comb filter hereafter. The main characteristics of the comb filter, as well as its advantages and disadvantages will be highlighted. Moreover, we will present the selected methods commonly used to decrease the disadvantages of the comb filters with minimum affectation of its advantages.

In the efficient implementation of the comb filter, a comb filter with transfer function based in (1) (just with the addition replaced by a subtraction) is employed. In order to avoid confusion, that filter will be referred hereafter as comb differentiator, since it is based on a simple first-order differentiator.

Background

Consider a simple FIR filter that has the following transfer function (Milic, 2009):

$$H(z) = \frac{1}{M} \sum_{k=0}^M z^{-k} \quad (3)$$

where M is the filter order. The coefficients that multiply the variable z are all equal to 1. Thus, the non-recursive implementation of this filter does not require *multipliers* for its coefficient's values. The impulse response of this filter is $h(k) = 1$ for $0 \leq k \leq M$ and 0 for other values of k . The scaling factor ($1/M$) is included to provide a normalized gain of 0 dB at frequency equal to zero.

The transfer function of the comb filter arises from expressing the transfer function given in (3) in recursive form as follows (Lyons, 2004):

$$H(z) = \frac{1}{M} \frac{1 - z^{-M}}{1 - z^{-1}} \quad (4)$$

This transfer function is the starting point for an efficient implementation of the filtering required in systems where the sampling rate is increased (upsampling) or decreased (downsampling). Both, the non-recursive structure to implement (3) and the recursive structure to implement (4) are shown in Figure 1.

In the context of digital filters, non-recursive means that the filtering structure does not require a feedback, whereas recursive means that the filtering structure has a feedback (i.e., the output depends on delayed versions of that output). Since the transfer function (3) and (4) are equivalent,

the comb filter is, in fact, the same. We observe from (4) that the recursive transfer function is the product of the terms $1/(1-z^{-1})$, which is an integrator, and $(1-z^{-M})$, which is a differentiator whose delay has been replaced by M delays. The frequency response of the comb filter is:

$$H(e^{j\omega}) = \frac{1}{M} \frac{\sin(\omega M / 2)}{\sin(\omega / 2)} e^{-j\omega(M-1)/2} \quad (5)$$

where ω is the normalized angular frequency.

The comb filter is very popular because it has the following advantages:

- It is a FIR recursive system, so it has linear-phase and guaranteed stability whenever the proper bus width is used (Lyons, 2004);

Figure 1. Filtering structures: (a) FIR comb filter in non-recursive structure and (b) recursive comb filter with an integration part and a comb differentiation part, where the delay z^{-1} has been replaced by z^{-M}

- It is multiplier-free and it only requires two additions (in fact they are subtractions, but *adders* and subtractors are considered with equal hardware complexity). Since *multipliers* are the most expensive elements in a filter, the comb filter can be used to design low-complexity multiplierless filters (Lyons, 2004);
- In the frequency range from $\omega=0$ to $\omega=\pi$, the zeros of the magnitude response of a comb filter are placed over the frequencies $\omega_k = 2\pi k/M$, for $k = 1, 2, \dots, \lfloor M/2 \rfloor$ ($\lfloor x \rfloor$ denotes the integer part of x). These zeros provide stopband regions with natural rejection to undesirable signals that are introduced into the band of interest when the sampling rate of such signals is decreased (an effect called aliasing) (Milic, 2009).

Due to the aforementioned characteristics in its magnitude response, the comb filter is commonly used as a multi-band filter, with one passband and several stopband regions. The passband, Ω_p , and the k -th stopband, $\Omega_{s,k}$, are given as follows:

$$\Omega_p = [0, \omega_p] \quad (6)$$

$$\Omega_{s,k} = [(2\pi k/M) - \omega_p, (2\pi k/M) + \omega_p] \quad (7)$$

where:

$$\omega_p \leq \pi/(2M) \quad (8)$$

$$k = 1, 2, \dots, \lfloor M/2 \rfloor \quad (9)$$

Nevertheless, the magnitude response of the comb filter is, in general, poor. These filters have the following disadvantages:

- The filter exhibits a passband droop that distorts the signals of interest;
- The useful stopband regions around the zeros of the comb filter are very narrow.

In order to improve the attenuation in the stopbands, K comb filters (commonly, the recursive blocks presented in Figure 1b) are used in cascade. However, this worsens the passband droop. As an example, Figure 2 illustrates the magnitude response of a comb filter with $M = 8$ and $K = 1, 2, 3$ and 4, where the bands of interest for the case $\omega_p = \pi/(2M)$ are enclosed into vertical rectangles. Note that the worst-case droop occurs in the right edge of the passband and the worst-case attenuation occurs in the left edge of the first stopband.

Active research has been developed in the last three decades to solve the aforementioned disad-

Figure 2. Magnitude responses of a comb filter with $M = 8$, $\omega_p = \pi/(2M)$ and $K = 1, 2, 3$ and 4

vantages. In the following section we detail the general objectives in this research line, along with two recent methods that are representative of it.

METHODS TO IMPROVE THE MAGNITUDE CHARACTERISTICS OF COMB FILTERS

Over the past three decades, research on comb filters has been carried out to improve the magnitude response characteristic of comb filters with the lowest increase in *computational complexity*. There are three different ways:

1. Improvement just in the passband region;
2. Improvement just in the stopband region; or
3. Improvement in both, passband and stopband regions.

In the following we explain some of the most representative and recent methods in these categories.

Magnitude Response Improvement in the Passband with Compensators

A compensator is a low-order filter that has every delay element replaced by M delays. The magnitude response of this filter compensates for the droop of the comb filter in the passband because it exhibits a raise from 0 dB inversely proportional to the passband droop.

The proposal of (Romero & Dolecek, 2013) presents a simple method to design compensation filters based on the cascaded interconnection of second-order subfilters that, even though exhibit a droop, only need three additions. The shape of the droop is inverted by using some extra coefficients and, for the case of using only one of these subfilters, a simple coefficient is used, which needs only one addition to be implemented. Thus, the resulting compensator requires 4 additions and corrects in an effective way the passband droop of comb filters independently of both, the value of M

Figure 3. Simple compensation filter with four additions

and the bandwidth of the passband. This second-order compensation filter is shown in Figure 3, where the values a_1 and a_2 represent variable shifts that change depending on the bandwidth of the passband.

To our knowledge, the simplest compensator available in scientific literature has been recently proposed by (Romero, Molina & Dolecek, 2015), and it is a first-order filter that requires only 2 additions. It corrects the passband droop independently of the value of M , but it works better for a narrow bandwidth of the passband. This filter also presents a desirable low delay property at expenses of a slight phase distortion. This filter is shown in Figure 4, where d represents variable shifts that change depending on the bandwidth of the passband.

Figure 4. Simple compensation filter with two additions

As a simple example, consider the case of $M = 16$, $\omega_p = \pi/(4M)$ and $K = 4$. Figure 5 shows the magnitude responses of the original comb filter, the compensation filter and the compensated comb filter with the four-adders compensator. Figure 6 presents similar graphs for the two-adders compensator. Clearly the compensated comb filters have a much better passband characteristic, achieved with a low additional computational cost. Also note that the attenuation remains almost equal in the original comb filters and in the compensated comb filters.

Magnitude Response Improvement in the Stopband Region

The proposal of (Coleman, 2012) is based on the stopband attenuation improved by modifying the cascade of K recursive comb filters with the addition of some extra coefficients and delay elements. Since the worst-case attenuation of the comb filter occurs in the left-side edge of its first stopband, the additional complexity allows improving the attenuation in this stopband, whereas the attenuation in the other stopbands is slightly degraded. At the end, all the stopbands have nearly the same attenuation, which is higher than the worst-case attenuation obtained with K cascaded comb filters.

Therefore, for the same worst-case attenuation, this scheme needs less cascaded comb filters than the traditional approach. As a consequence, the overall filter uses a narrower bus width.

Coleman presented the mathematical framework that allows having a simple method to obtain the values of the additional coefficients using the N -th degree Chebyshev polynomials, $T_N(x)$, which can be easily calculated with the following recursive formula (Coleman, 2012):

$$T_0(x) = 1 \quad (10)$$

$$T_1(x) = x \quad (11)$$

$$T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x) \quad (12)$$

With this, no intricate optimization method is needed. The value N indicates the number of cascaded comb filters, and the polynomial coefficients represent the extra complexity added to the N cascaded comb filters.

Let us consider a simple example where $M = 16$ and $\omega_p = \pi/(2M)$. Figure 7 shows the magnitude responses of the original comb filter with $K = 7$, and the modified comb filter with $N = 5$.

Figure 5. Magnitude responses of the comb filter, the compensation filter and the compensated comb filter (four-adders compensator), for $M = 16$, $\omega_p = \pi/(4M)$ and $K = 4$

Figure 6. Magnitude responses of the comb filter, the compensation filter and the compensated comb filter (two-adders compensator), for $M = 16$, $\omega_p = \pi/(4M)$ and $K = 4$

Note that both filters have 70 dB of worst-case attenuation. However, the modified comb filter uses 5 cascaded comb filters in comparison to the traditional comb filter where 7 cascaded comb filters are used.

Simultaneous Magnitude Response Improvement in Passband and Stopband

The sharpening technique permits simultaneous improvements of both, passband and stopband

characteristics. This technique is based on an Amplitude Change Function (ACF) which is a polynomial $P_{m,n}(x)$ that maps the amplitude x into an improved amplitude $y = P_{m,n}(x)$. The improvement in the amplitude near to the passband depends on m , the order of tangency of the ACF at the point $(x, y) = (1, 1)$ to a line with slope equal to zero. Similarly, the improvements in amplitudes near the stopband depend on the order of tangency of the ACF at the point $(x, y) = (0, 0)$ to a line with slope equal to zero, which is denoted as n . The polynomial approximation to the desired ACF also

Figure 7. Magnitude responses of the comb filter and the modified comb filter by (Coleman, 2012), for $M = 16$, $\omega_p = \pi/(2M)$, $K = 7$ and $N = 5$

is controlled by other two parameters, namely, σ , the slope of a line that passes over the point $(x, y) = (1, 1)$ and δ , the slope of another line that passes over the point $(x, y) = (0, 0)$. The constraints on the approximating polynomial $y = P_{\sigma, \delta, m, n}(x)$ are:

1. The n th-order tangency at $(x, y) = (0, 0)$ to the line of slope δ , i. e., $P_{\sigma, \delta, m, n}(x) \approx \delta x$, for $x \approx 0$;
2. The m th-order tangency at $(x, y) = (1, 1)$ to the line of slope σ , i. e., $P_{\sigma, \delta, m, n}(x) \approx \sigma(x - 1) + 1$, for $x \approx 1$.

A general formula was deduced by (Samadi, 2000) to obtain directly the desired amplitude change function from the design parameters. The formula is given by:

$$P_{\sigma, \delta, m, n}(x) = \delta x + \sum_{j=n+1}^R (\alpha_{j,0} - \sigma \alpha_{j,1} - \delta \alpha_{j,2}) x^j \quad (13)$$

where $R = n + m + 1$ and:

$$\alpha_{j,0} = \sum_{i=n+1}^j (-1)^{j-i} \binom{R}{j} \binom{j}{i}, \quad \alpha_{j,1} = \sum_{i=n+1}^j (-1)^{j-i} \binom{R}{j} \binom{j}{i} \left(1 - \frac{i}{R}\right), \quad \text{and} \quad \alpha_{j,2} = \sum_{i=n+1}^j (-1)^{j-i} \binom{R}{j} \binom{j}{i} \frac{i}{R} \quad (14)$$

with:

$$\binom{n}{k} = \frac{n \times (n-1) \times \cdots \times 1}{[k \times (k-1) \times \cdots \times 1] \times [(n-k) \times (n-k-1) \times \cdots \times 1]} \quad (15)$$

The simultaneous improvement of the passband and stopband characteristics of a comb filter presented by (Jimenez & Dolecek, 2013) and (Jimenez & Dolecek, 2015) consists in splitting that filter into stages, and then using the aforementioned improved sharpening technique on the last stage comb filter, which is previously compensated. The sharpening polynomials are translated to cascaded compensated comb filters aided with low-complexity coefficients. The resulting architectures resemble that of Coleman's filters presented in the previous section, but a much better improvement in passband and stopband is achieved. Usually, this comes at the cost of a more complex architecture.

A simple example to illustrate the sharpening technique is given in Figure 8. The sharpening polynomial uses tangencies $m = 1$, $n = 3$, $\sigma = -1$ and $\delta = 0$ and it is compared with a comb filter where $M = 16$, and $K = 6$. The passband edge is $\omega_p = \pi/(2M)$. Note that both filters accomplish 60 dB, but the sharpened filter has a compensated passband droop.

Figure 8. Magnitude responses of the comb filter with $K = 7$ and the modified comb filter by (Jimenez & Dolecek, 2013), for $M = 16$ and $\omega_p = \pi/(2M)$

FUTURE RESEARCH DIRECTIONS

A comb filter is a basic building block with a simple and hardware-efficient structure. However, its disadvantages are its magnitude characteristics. One of the most common applications of the comb filters presented in this chapter is as anti-aliasing filters in decimation processes. In these cases, the filter is placed before the downsampling process. Since the filtering incur in higher power consumption as their sampling frequency operation grows, a traditional anti-aliasing filter may consume high power. The recursive structure of the comb filter is effective because its comb differentiator part can be moved to the low-rate section (in that case, only one delay z^{-1} is used, instead of the M delays shown in Figure 1b). However, the integrator part still works at high rate. Decreasing the computational complexity of these filters is a topic that has received much attention in current research (Molina, Dolecek & De La Rosa, 2014). Thus, one of the recent insights has been using the comb filter in its non-recursive form and decomposing it in subfilters that can work at the lower sampling rate section. This design scheme is generally known as polyphase decomposition (Milic, 2009).

The non-recursive form and polyphase decomposition of the comb filter has the disadvantage of demanding much chip area. Thus, a wise research path to be pursued is combining non-recursive and recursive structures of modified comb filters. In this way, the power and area demand can be lowered and, simultaneously, the modified comb filter can provide better magnitude characteristics than its traditional version.

CONCLUSION

The concept of comb filter was introduced in this chapter. We showed that comb filter is a general term that encloses several types of filters, including Finite Impulse Response (FIR) and Infinite

Impulse Response (IIR) systems. These filters share a common characteristic: their magnitude responses resemble the teeth of a comb. Additionally, the simplest FIR and IIR comb filters have been presented.

This chapter was mainly focused on illustrating the characteristics of the comb filter based on the moving average low-pass filter, which has unitary coefficients. Then, the efficient recursive form of this filter was presented, which requires only two addition operations. This structure represents the main advantage of the comb filter. However, its disadvantage is the poor characteristics of its magnitude response.

Four recent methods to improve the magnitude characteristic of comb filters have been introduced. The first two methods, based on the use of compensation filtering, correct the passband droop of the original comb filter. The third method uses Chebyshev polynomials to increase the worst-case attenuation of the original comb filter, whereas the fourth method uses sharpening polynomials to perform both improvements: droop correction and stopband attenuation. These methods have been illustrated with examples. The end of the chapter presents the future research directions on the design of comb-based FIR filters that are applied as anti-aliasing filters in decimation processes.

There are many existing methods that use comb filters for applications in, for example, audio, digital communications or analog to digital data conversion. In this chapter we have presented a concise introduction of comb filters, which can serve as a useful door to enter into the fascinating world of efficient processing of digital signals based on comb filtering.

KEY TERMS AND DEFINITIONS

Adder: Is a component of a digital filter that produces at its output the sum of the values of the samples present at its inputs.

Complex Exponential Signal: A signal whose samples are complex numbers, where the real and imaginary parts of the samples form, respectively, a cosine wave and a sine wave, both with the same frequency.

Complex Function: A function whose values are complex numbers.

Complex Number: Is a number composed by the sum of a real number a and an imaginary number $i \times b$, where b is a real number and i is defined as the square root of -1 .

Computational Complexity: Is the number of arithmetic operations that a filter performs

to obtain an output sample. The computational complexity is proportional to both, the power consumption of the filter and the speed of operation. Thus, this complexity must be decreased in practical applications.

Delay: Is the retention of a sample of a digital signal during a sampling period T_s and the subsequent release of that sample at the next sampling period. This is done with a one-input one-output device called delay. In other words, for a signal $x(nT_s)$, its delayed version is $y(nT_s) = x(nT_s - T_s)$. In a block diagram, this element is represented as z^{-1} . A block of M delays is represented as z^{-M} .

Digital Filter: Is a system that receives a digital signal and returns another digital signal with modified characteristics.

Digital Frequency: Is a value that expresses how much of a cycle of a sinusoidal wave is represented by a sample. This value is denoted by f . For example, $f = 1/2$ means that 2 samples of a digital signal correspond to a sinusoidal cycle. If, instead of cycles we use radians, we obtain the angular digital frequency denoted as ω , which is equal to $2\pi f$.

Digital Signal: Is a sequence of numbers, so-called samples, where every sample lasts T_s seconds. The time T_s is called sampling period and the number produced in the n -th sampling period (i.e., after n times T_s seconds) is denoted as $x(nT_s)$. The values $x(nT_s)$ are constrained to belong to a finite set of possibilities (for example, in a 1-bit signal, these values are just 0 or 1). Additionally, it is usual to consider that $x(nT_s) = 0$ for negative values of n . For analysis purposes, it is usual to consider $T_s = 1$.

Frequency Response: Is the response of a Linear Time-Invariant (LTI) digital filter to a complex exponential signal with frequency $\omega = 2\pi f$. Generally, the frequency response is a complex function of ω . The frequency response is a periodic function of ω with period 2π . Thus, for analyzes it is necessary to describe the frequency response just in the interval of ω from $-\pi$ to π . When the samples of the impulse are real numbers, the frequency response is described just in the interval

of ω from 0 to π because of the symmetries of its magnitude and phase responses. The frequency response is usually denoted as $H(e^{j\omega})$.

Impulse Response: Is the response of a Linear Time-Invariant (LTI) digital filter to an input signal $x(nT_s)$ that has the value 1 for $n = 0$ and 0 for other values of n . The samples of the impulse response are usually denoted as $h(nT_s)$.

Magnitude Response: Is a function of the angular frequency ω where every value is obtained as the magnitude of the complex value of the frequency response in that frequency ω . If the value of the frequency response in ω is a complex number of the form $a(\omega) + i \times b(\omega)$, the magnitude of that number is given by $\{[a(\omega)]^2 + [b(\omega)]^2\}^{1/2}$. When the samples of the impulse are real numbers, the phase response is symmetric and hence it is described just in the interval of ω from 0 to π .

Multiplier: Is a component of a digital filter that takes the samples at its inputs and produces the multiplication of these values at its output. A multiplier is an expensive and power-consuming element, and therefore the efficient design of digital filters consists on reduce the number of required multipliers or even avoid them.

Phase Response: Is a function of the angular frequency ω where every value is obtained as the phase of the complex value of the frequency response in that frequency ω . If the value of the frequency response in ω is a complex number of the form $a(\omega) + i \times b(\omega)$, the phase of that number is given by $\arctan\{b(\omega)/a(\omega)\}$. When the samples of the impulse are real numbers, the phase response is anti-symmetric and hence it is described just in the interval of ω from 0 to π .

Scaling: Is the change of the range of values that a signal can take. For example, if a signal can take values from -1 to 1 and that signal is scaled by 5 , the scaled signal can take values from -5 to 5 .

Transfer Function: Is a mathematical representation of the relation of a Linear Time-Invariant (LTI) digital filter between its input and its output. The transfer function is expressed in terms of the variable z , which can take complex values. If the values for z are constrained to be complex numbers with unitary magnitude, the transfer function becomes the frequency response. The transfer function is usually denoted as $H(z)$.

Consumer Adoption of PC-Based/Mobile-Based Electronic Word-of-Mouth

M**Akinori Ono***Keio University, Japan***Mai Kikumori***Ritsumeikan University, Japan*

INTRODUCTION

Word of mouth (WOM) is one of the most fascinating topics for marketing scholars and practitioners (cf. Ono and Kikumori, 2015). WOM is defined as oral, person-to-person communication between a receiver and a communicator whom the receiver perceives as non-commercial, concerning a brand, a product or a service (Arndt, 1967, p.3). Previous studies on WOM have found that it can have a great impact on consumer attitude formation, purchase decisions, and even post-usage perceptions of a product or service (e.g., Katz & Lazarsfeld, 1955; Brown & Reingen, 1987; Herr, Kardes, & Kim, 1991; Bone, 1995).

Since the advent of the internet in the early 1990s, electronic word of mouth (eWOM) has become extremely important (Bickart & Schindler, 2001; Godes & Mayzlin, 2004). Consumers increasingly communicate product information with other consumers via new forms of communication, including e-mail, community sites, review sites, social networking sites, blogs, online discussion forums, and news groups (e.g., Goldsmith, 2006; Okazaki, 2008). Many scholars have found that eWOM messages about products and services can have a great impact on purchase decision-making (Cheung, Lee, & Rabjohn, 2008; Park & Kim, 2008; Schlosser, 2011; Sen & Lerman, 2007).

Moreover, with the rapid growth of mobile phone ownership, an increasing number of consumers can communicate with others and

send and receive product information through their mobile phones (cf. Shen, Wang, & Xiang, 2013). Communication via mobile phones in the form of e-mail, SMS, and text messages has the unique characteristic of ubiquitous connectivity, which enables consumers to exchange information anytime and anywhere (Lee, 2005; Okazaki, 2008). Therefore, mobile-based electronic word of mouth (mWOM) is now regarded as an important mobile marketing tool for offering consumers context-sensitive and time-critical recommendations (Okazaki, 2009).

Viral marketing campaigns, which are defined as distribution or communication that relies on consumers to transmit content via electronic communication techniques to other potential consumers in their social sphere and to animate these contacts to also transmit the content, have been a focus for pioneers of eWOM research (Wiedemann, 2007, p.53). Most research on PC-based viral marketing campaigns has qualitatively investigated how recipients of viral messages from marketers via friends and relatives adopt and send messages (Phelps, Lewis, Mobilio, Perry, & Raman, 2004). Several studies have also constructed and tested a causal model that explains why recipients adopt and send viral messages (Ho & Dempsey, 2008). In addition, some studies have focused on what determines consumers' intentions to participate in mobile viral marketing (Okazaki, 2008), and have tried to describe the entire consumer decision-making process for mobile viral marketing cam-

paings across multi stages (Wiedemann, Palka, & Pousttchi, 2008; Palka, Pousttchi, & Wiedemann, 2009; Pescher, 2014).

The determinants of eWOM adoption have also been investigated. Some eWOM studies have investigated what determines the intention to adopt eWOM messages on the Web (Cheung, Lee, & Rabjohn, 2008), whereas more recent studies have focused on how recipients of mWOM reviews from anonymous message senders evaluate and adopt the reviews (Shen, *et al.*, 2013; Wang, Shen, & Sun, 2013).

This chapter examines previous studies that have tried to answer why consumers adopt PC-based/mobile-based eWOM messages or participate in PC-based/mobile-based viral marketing campaigns. Our understanding can be enhanced by re-examining the findings of the current leading scholars.

BACKGROUND

Consumer Intention to Participate in PC-Based Viral Marketing

Viral Marketing is defined as marketing that ‘infects’ its customers with an advertising message, which passes from one customer to the next like a rampant flu virus (cf. Montgomery, 2001). Recently, marketing scholars have investigated various topics relating to viral marketing (e.g., Chiu, Hsieh, Kao, & Lee, 2007; Gangadharbatla & Lisa 2007; Hinz, Skiera, Barrot, & Becker, 2011; Huang, Lin, & Lin, 2009; Phelps, *et al.*, 2004). As pioneers in these studies, Dr. Phelps at the University of Alabama and his colleagues (Phelps, *et al.*, 2004) examined what the motives were that caused consumers to pass along the email marketing messages they had received. The results of in-depth interviews showed that the most common motivations were fun, including enjoyment and entertainment, and social connection, such as helping others and to communicate caring.

The earliest studies on viral marketing focused on the demographic, psychographic, and behavioral characteristics of mobile phone users engaged in viral marketing behavior (e.g., Chiu, Lee, & Chen, 2006; Dobeles, Lindgreen, Beverland, Vanhamme, & van Wijk, 2007; Phelps, *et al.*, 2004; Wiedemann, 2007; Wiedemann, *et al.*, 2008). As pioneers who addressed this gap, Dr. Ho at Simon Fraser University and Dr. Dempsey at Ryerson University (Ho & Dempsey, 2008) identified four motives involved in forwarding online content (the need to belong, individuation, altruism, and personal growth) based on the FIRO (fundamental interpersonal relations orientation) theory (Schutz, 1966), which identified three motives—inclusion, affection, and control. They proposed a causal model describing that these four motives, as well as the amount of online content consumed due to curiosity, affect the frequency of forwarding online content (Fig.1). The results of structural equation modeling showed that three of five direct motives—individuation, altruism, and the amount of online content consumed—had significant and positive impacts on the frequency of forwarding online content. However, the need to belong and curiosity were insignificant factors. Moreover, contrary to the proposed hypothesis, the impact of personal growth on the frequency of forwarding was negative.

Consumer Intention to Participate in Mobile Viral Marketing

The pioneering studies of consumer intention to participate in mobile viral marketing were conducted by Dr. Okazaki (Okazaki, 2008) at the Autonomous University of Madrid. He modeled causal relationships among user characteristics, perceived values, attitudes, intentions, and consumer behaviors in those who send mWOM messages and participate in mobile viral marketing. He modeled three exogenous variables (commitment to promoted brand, relationship with mobile devices, and group-person connectivity) as indirect determinants of the attitude-intention-behavior

Figure 1. Ho and Dempsey's model (2008)

Source: Ho & Dempsey (2008), p.1003

chain using two kinds of values (entertainment/hedonic and purposive/utilitarian) in the mobile viral marketing campaign (Fig.2). The proposed model was empirically tested using structural equation modeling, and the results showed that all paths are significant. Therefore, the proposed model was supported. In addition, Dr. Okazaki performed a multi-group analysis among users whose information sources were different from each other. The findings showed that only two

paths were statistically different between people who use e-mail magazines as an information source and those who pass-along e-mail. In contrast, all paths were statistically different between people who use pass-along e-mail as an information source and those who use direct referral.

Like Dr. Okazaki (2008), Dr. Yang and Dr. Zhou (Yang & Zhou, 2011) at Appalachian State University proposed a causal model describing the determinants of consumer intentions to participate

Figure 2. Okazaki's model (2008)

Source: Okazaki (2008), p.718.

Figure 3. Yang & Zhou's model (2011)

Source: Yang & Zhou (2011), p.89.

in mobile viral marketing and their actual behavior with regard to forwarding mobile viral messages. Based on the theory of planned behavior (Ajzen, 1991), they modeled three determinants (attitude, subjective norm, and perceived behavioral control) of consumer intention toward forwarding mWOM messages and the frequency of forwarding mWOM messages in the context of mobile-based viral marketing. They also modeled three additional determinants—perceived usefulness, ease of use, and perceived cost (cf. Davis, 1989; Palka, *et al.*, 2009) (Fig.3). The results of structural equation modeling showed that three of the five proposed exogenous variables (subjective norm, behavioral control, and perceived cost) affected viral marketing attitude, intent, and behavior. In addition, perceived usefulness directly affected intent. Unfortunately, all other paths were insignificant.

Multi-Stage Consumer Referral Process in Mobile Viral Marketing

Dr. Wiedemann, Dr. Palka, and colleagues at the University of Augsburg proposed a customer funnel-type process model named the “basic model (or grounded theory) of mobile viral

marketing process” that described a consumer’s psychological flow. After a presentation at a conference (Wiedemann, *et al.*, 2008), they published a paper regarding their model (Palka, *et al.*, 2009). Whereas the researchers mentioned in the previous section constructed and tested causal models to explain why a consumer forwards viral marketing messages to friends and relatives, their studies focused on illustrating the entire consumer decision-making process, which consists of receiving, using, and forwarding a mobile viral marketing message (Fig.4). They developed not only the three-stage comprehensive process model but also detailed models. The receipt model, one of the three detailed models, was proposed to describe six elements of three kinds of conditions (perceived risk and trust as security-related conditions, sender recognition and perceptual affinity as social conditions, and self-efficacy and perceived cost as resource-based conditions) grounding a recipient’s intention to open the mobile viral marketing message (Fig.5).

Like Dr. Palka and colleagues, Dr. Pescher (Pescher, 2014) at Ludwig Maximilian University, Munich, modeled the entire consumer decision-making process for a mobile viral marketing

Figure 4. The basic model of a mobile viral marketing process

Source: Palka, et al. (2009), p.175

campaign via mobile phones across multiple stages (Fig.6). While Dr. Palka and colleagues modeled three stages of receipt, usage, and forwarding of mobile viral marketing messages, Dr. Pescher modeled reading, interest, and decision to refer, based on traditional consumer decision-making models (cf. Bettman, 1979). The results of sequential logit modeling showed that (1) the first stage (receipt and reading) was determined by entertainment value (Okazaki, 2008) and tie strength (Granovetter, 1973); (2) the second stage (interest and use) was determined by entertainment value and purposive value (Okazaki, 2008); and (3) the final stage (intention to forward) was determined by entertainment value, purposive value, tie strength, and usage intensity, which referred to the number of text messages sent via mobile phones per day (Steenkamp & Gielens, 2003).

CONCLUSION

Consumer Intention to Adopt eWOM Messages

Dr. Cheung at Hong Kong Baptist University and colleagues (Cheung, *et al.*, 2008) examined

factors that determined consumer willingness to accept and adopt eWOM messages within online communities. Using dual-process theories (Sussman and Siegal, 2003; Bhattacharjee and Sanford 2006), they proposed a causal model describing four factors of argument quality and two factors of source credibility that affect perceived usefulness and, in turn, adoption of eWOM messages within online communities (Fig.7). The results of Partial Least Squares modelling showed that two of four argument quality factors (relevance and comprehensiveness) had positive impacts on information usefulness, which in turn positively affected information adoption. Unfortunately, all other paths were not statistically significant.

Consumer Intention to Adopt mWOM Applications and Messages

Several recent studies have focused on how recipients of mWOM reviews from anonymous message senders evaluate and adopt the reviews. Of these studies, Dr. Shen at Wuhan University, Dr. Wang at the University of Science and Technology of China, and a colleague (Shen, *et al.*, 2013) examined the effects of the mobile device system and information characteristics on consumer perceptions

Figure 7. Cheung, et al.'s model (2008)

Source: Cheung, et al. (2008), p.233

of ubiquitous decision support systems. Based on the IS success model (DeLone & McLean, 1992), the technology acceptance model (Davis, 1989), the information adoption model (Davis, 1989), and the human-computer interaction literature (Li & Yeh, 2010), Dr. Shen and colleagues proposed a causal model to identify factors influencing consumer intentions to use mWOM applications and adopt mWOM reviews (Fig.8).

The results of structural equation modeling showed that two explained variables—consumer

intentions to use the mobile review application (system adoption) and adopt mWOM reviews (information adoption)—were directly determined by system and information usefulness. System usefulness had a stronger impact on system adoption, whereas information usefulness had a stronger impact on information adoption. The results also showed that three out of five system characteristics (wireless network stability, physical appearance of mobile devices (Yun, Lee, Kim, & Kettinger, 2011), and design aesthetics of the

Figure 8. Wang, et al.'s model (2013)

mobile application (Cyr, Head, & Ivanov, 2006)) significantly predicted system quality, which in turn determined system usefulness. In contrast, all three information characteristics (localization, immediacy, and customization of the information obtained from the system) were major predictors of information quality, which in turn determined information usefulness.

In another article, Dr. Shen, Dr. Wang, and a colleague (Wang, *et al.*, 2013) investigated the process of trust transfer between PC- and mobile-based eWOM services and its role as a determinant of intention to use the services. From the trust transfer perspective, they proposed a causal model explaining that the initial trust in PC-based eWOM services as well as two factors regarding the relationships between the source and target of trust transfer (functional consistency and perceived entitativity) affect trust in mWOM services, which in turn predicts user intentions to use the mWOM services (Fig.9). They also added the perceived value of mWOM services as a control variable to their model.

The results of structural equation modeling showed that consumer trust in PC-based eWOM services had a significant, positive impact on consumer trust in mobile-based eWOM services,

which in turn affected consumer intention to use the mobile-based eWOM services. These results suggest that consumer trust in PC-based eWOM services can be transferred to mobile-based eWOM services. The results also showed that functional consistency between PC-based and mobile-based eWOM services and perceived entitativity had a significant, positive impact on consumer trust in mobile-based eWOM services. Moreover, functional consistency enhances perceived entitativity. When users perceive that the relationship between two kinds of eWOM services is strong, they are more likely to trust in mWOM services, given their initial trust in PC-based eWOM services.

FUTURE RESEARCH DIRECTIONS

There is still room for future research on consumer adoption of eWOM/mWOM messages. First, previous studies have not compared eWOM to mWOM. Most studies have not even referred to possible differences between eWOM and mWOM. Future research should examine the influences of receiving a message on a desktop PC vs. a mobile device on consumer adoption of the message.

Second, research methods should be re-examined. For example, most previous studies on mWOM conducted PC-based surveys, not mobile-based surveys, to collect data. Furthermore, both survey sampling design and experimental design should be used to conduct empirical tests. In addition, most previous studies have investigated a single product category. Future research should consider differences among products in terms of consumer involvement and knowledge. Moreover, researchers should take into account that this is just the beginning of internet marketing. The findings of the previous research may change with the increasing prevalence of eWOM and the related marketing activities.

Finally, research on consumer adoption of eWOM should be expanded to include the choice of brand/store that is adopted. Several studies have already begun investigating the impact of adopted eWOM message characteristics, such as the ratio of positive to negative messages, on consumer attitudes toward the brand (cf. Kikumori & Ono, 2013). However, the impact of mWOM characteristics on consumer choice has not yet been sufficiently investigated. Future research should be conducted to determine the impact of mWOM as well as the differences between eWOM and mWOM (cf. Ono, Nakamura, Okuno, & Sumikawa, 2012).

KEY TERMS AND DEFINITIONS

Word-of-Mouth (WOM): Any positive, neutral, or negative messages sent by potential, actual, or former customers about a product, company, or users, which is made traditionally in oral form or, in a broader sense, in written form via the Internet.

Electronic Word-of-Mouth (eWOM): WOM sent via the Internet, which is made available to

an unspecified number of people by using online review platforms, or to particular persons by using e-mail, short mail services (SMS), or social networking sites (SNS),

Mobile Electronic Word-of-Mouth (mWOM): eWOM sent and/or received using mobile devices, such as cellphones, smartphones, and tablet computers.

Consumer Intention to Adopt eWOM/mWOM Messages: The degree to which consumers intend to closely follow eWOM/mWOM messages and be motivated to take action.

Mobile Viral Marketing: The transmission of mobile advertising in the form of consumer referral of promoted content.

Consumer Referral Behavior: The processes by which consumers send WOM messages related to a viral marketing campaign to friends or acquaintances.

Mobile-Based eWOM Services: Online review platforms provided by a firm in the mobile context where consumers can exchange eWOM.

Context-Aware Personalization for Mobile Services

INTRODUCTION

The last decade has witnessed an unprecedented proliferation of multimedia-enabled mobile devices and an escalation of online multimedia content. In fact, consumption of audiovisual content in diverse mobile platforms has risen exponentially and this trend is expected to continue in the next few years as mobile devices become more and more sophisticated. According to Gartner, a world leading information technology research and advisory company, *Smartphone* sales represented two-thirds of global *mobile phone* market in 2014 with over 1.2 billion units sold (Gartner, 2015). Thus, it appears, smartphones are gradually replacing our desktops as they increasingly become cheaper and more powerful (in terms of processing capability, network connectivity) with excellent multimedia processing support (Flora, 2010; Ricci, 2011). This development indicates global penetration and increasing acceptance of smartphones as the primary platform for information access and processing.

As mobile users go about their daily routines, they continuously browse the Web, seeking interesting content to consume, and occasionally also uploading their personal content. However, users encounter huge volume of content, which often does not match their preferences resulting in what we call *mobile information overload*. To address this problem, user preferences are usually learned to predict relevant content. However, user preferences are dynamic, changing as users move from

one place to another, performing different activities. Therefore, it is important to mine, learn and understand contexts in which users perform such activities. This contextual information can be used to filter, customize and deliver interesting content, the process generally referred to as context-aware personalization. Its main goal is to assist users to overcome mobile information overload by selecting from overwhelming set of potential choices, services, etc. that match user's context dependent content to target users, tailoring such services to user's tastes, network and device characteristics. Consequently, users can focus more on important activities, minimizing distractions and time, while consuming multimedia services.

Context-aware media personalization (CAMP) has been the focus of researchers addressing mobile multimedia information overload problem in the last years (Ricci, 2011; Otebolaku & Andrade, 2015a; Lee et. al, 2015). CAMP assists users to select content among a deluge of alternatives by considering users' preferences and contexts to improve their consumption experience. Existing solutions of this kind, however, are limited to static preferences. The traditional personalization solutions only consider user preferences without contexts such as location, activities, etc. Static solutions are not effective in mobile environments as users are increasingly mobile, moving from one location to another, engaging in diverse activities. For example, the type of content a user would consume at home would be, in most cases, different from those they would consume in the office

or at airports. Even those solutions that consider contexts have relied on explicit *contextual information*. For example, they usually ask users to provide their current contexts. Systems relying on this kind of static context information have not been able to address information overload problem. Thus, our contribution to CAMP is *Mobile Context-Aware Media Personalization* (MobCAMP), which we define as a special type of personalization that utilizes user's contexts and activities to select and adapt media content according to user's tastes and contextual situations. Recommendation algorithms currently are the most popular techniques for realizing personalization, whilst context-aware recommendations deal with providing suggestions to users when and where content are needed, context-aware personalization can be used to provide such suggestions when, where and how such content is required.

MobCAMP is proposed as an extension of our previous solution (Otebolaku and Andrade, 2015b), built on a number of existing technologies. First, rapid development in the field of mobile and telecommunication networks enabled ubiquitous communications whereby smartphone users can connect to the Web and consume services anywhere, anytime. With this development, users can access content such as news, music, movies, etc. at their convenience. Second, mobile devices now come with cheap, built-in sensors, enabling ubiquitous context sensing (Otebolaku & Andrade, 2016; Kwapisz et. al., 2010). Sensors such as thermometers, accelerometer (sensing movement), and GPS sensor (sensing location), etc. now ship with smartphones. Third, context-awareness has enabled the ability to deliver personalized information based on user's contextual situations. Information such as location, activity, time, weather, etc. can now be obtained readily in real-time from smartphones. Fourth, traditional recommendation systems have matured, and are helping users to find relevant information (Adomavicius et. al., 2005). These solutions can be explored to realize context-aware mobile multimedia personalization. Thus, MobCAMP builds on these core solutions,

using mobile user's preferences to suggest useful and interesting content, tailored to users' contextual situations.

Let us consider a scenario to illustrate this concept.

Carisa is an Electrical Engineering student of the University of Porto. She lives at the city outskirts, and catches a train every morning at 7:30 AM to the campus in time to attend 9:00 AM lecture. Before leaving home, while taking her breakfast, Carisa normally checks weather forecast. On her way walking to the train station she listens to country music, whereas on the train Carisa prefers to read breaking news. From the train stop, while walking, to the campus she profits from listening to her favorite music. However, when she is in the classroom she switches her mobile phone to silent mode. Then, on her way back home in the evening, she also enjoys listening to music except on Fridays when she eagerly seeks for good movies playing in the theaters near her home or in downtown Porto provided the weather forecast indicates a dry weekend.

In the presented scenario, it is important to capture *Carisa's* activities such as walking, time, 9:00 AM, preferably at a higher level, e.g. morning. *Carisa's* location should also be inferred from GPS or Wi-Fi. MobCAMP is designed to obtain this information dynamically and use it to suggest and customize relevant content to *Carisa*.

This chapter presents MobCAMP, a system for suggesting Web-based multimedia content to mobile users based on context recognition, contextual user profiling, and adaptive context-aware recommendation processes.

BACKGROUND

Traditional personalized recommendation systems aim at guiding users to the most relevant items but they do not take contextual information into account (Adomavicius et. al., 2005). Personalized

recommendation systems can build, manage, and represent information, customized to a particular user. Personalization grew mainly out of information retrieval system community to minimize information overload and to retain customers by anticipating their content needs. As succinctly put by Burke in (Burke, 2002), the criteria *individualizing*, *interesting*, and *useful* information distinguish personalized recommendation systems from retrieval systems. If we remove personalization from recommendation processes, we are left with only a set of popular items, which are independent of users' desired tastes. Therefore, on the one hand, in information retrieval systems such as search engines, the results that are relevant to a query usually do not change irrespective of the individual who issues such query or where and when it is issued. On the other hand, in traditional recommendation systems, the results of a query are usually a set of popular items.

The traditional personalized recommendation techniques can be broadly categorized into three (Adomavicius & Tuzhilin, 2005): 1) based on the opinions and preferences of other users, designated as Collaborative Filtering (CF) (Schafer et. al., 2007); 2) based on user's consumption history and the descriptions of available candidate items, referred to as Content Based Recommendation (CBF) (Pizzani & Billsus, 1997); and 3) based on a combination of CF and CBF denoted as Hybrid Recommenders (HR).

Personalized collaborative systems traditionally suggest items to target users based on how similar users have rated the same items. Formally, rating $R(u, i)$ is predicted based on rating $R(u', i)$ given to the same item i by user u' who is similar to user u (Adomavicius & Tuzhilin, 2005). CF is broadly categorized into 2: Memory-based and model-based collaborative systems. The former uses heuristics to make predictions based on the entire collection of previously rated items, whereas the latter uses collection of previously rated items to learn a model to provide recommendations for users. Because they load the entire dataset into system's memory for processing, memory-based

CF systems are computationally expensive, especially when a large number of users or items are involved. On the other hand, model-based CF requires less computational resources, in addition to having shorter response time. Memory-based CF, nevertheless, produces more accurate predictions than a model-based CF (Adomavicius & Tuzhilin, 2005). A good example of CF system is GroupLens (Resnick et. al., 1994).

Personalized content-based systems utilize user's preferences to analyze candidate items to identify similarity between a target user and candidate items (Adomavicius & Tuzhilin, 2005). Only items with a high degree of similarity to the target user's profile are recommended. A user profile describes preferences of the user, based on the history of the user's actions (Alberto, 2010). However, one major drawback of CBF is that of over specialization (Adomavicius & Tuzhilin, 2005). This means that a target user can be presented only with recommendations that are similar to those items he has rated in the past. From user's perspective, this method provides boring or stale recommendations. Users always want to try out new items based on their present environment and situations. Pizzani & Billsus (2007) presents a detailed survey of CBF systems.

Personalized hybrid recommendation systems use a combination of item ratings provided by user and ratings of items consumed by her so-called neighbors or friends in the past to compute recommendations. Combining CF and CBF techniques, HR was developed to address the weaknesses of both CBF and CF, such as over specialization problem of CBF and the new user problem of CF (Adomavicius & Tuzhilin, 2005). However, these personalization techniques' effectiveness has been limited by weaknesses (e.g. absence of rating information, and lack of contextual information) of the constituent techniques it incorporates (Yu et. al, 2007). Good examples of hybrid recommender systems can be found in a survey conducted by Burke R. (2002).

Recently, new approaches incorporating contextual information have emerged to address

weaknesses of traditional recommendation techniques (Adomavicius et. al., 2005). In traditional recommendation systems, *user preferences* are considered as static information. This assumption means that a user who likes a specific item in the past will always like the same item or similar items in the future. This assumption does not hold, especially in a mobile environment where user preferences change with contextual situations (Said et al., 2011). For example, a user who likes watching movies when at home every weekend, would most likely not indulge in watching movies when in the office. She would rather probably prefer to listen to music. Therefore, it is important to capture, in real-time, this contextual information and relate it to the preferences of users to suggest interesting content, which are relevant to user preferences in context.

This problem has been explored extensively by many researchers in recent time. Adomavicius et al. (2005) pioneered and proposed the incorporation of contextual information into recommender systems, using a multidimensional approach. Additionally, Chen (2005) proposed a context-aware collaborative recommendation technique that computes similarity between context where a target user has rated an item and his present context to recommend new items. It looks at what like-minded users have done in the past under similar contexts (e.g., location, weather) to suggest interesting items. Nevertheless, generating similarity between contexts can be unrealistic in some application domain, especially when ratings of items consumed in such contexts are not available (Vallet et al., 2007). Another important part of the system is user profiling, which summarizes consumption history of a user and her preferences. Generally, it refers to a collection of long or short-term data associated with a specific user or a group of users (Alberto, 2010). Existing user profiling approaches do not consider the relationship between consumption contexts and user preferences. Therefore, they do not support contextual recommendations. Said et. al. (2011) proposed a solution incorporating contexts into

user profile to describe user preferences according to the contextual situations where such preferences are expressed. This solution is one of the latest attempts to address this problem.

Most of those solutions, however, require users to regularly provide their contextual information, with an assumption that such contextual information is readily available. However, this is not a realistic solution in practice. For example, it is not convenient to ask a user to supply information such as “I am walking near home, wanting to watch a drama movie alone”. This puts extra burden on users, causing distraction and ultimately ineffectiveness. Users would prefer such system to automatically infer their contextual situations to suggest relevant content, using notifications without distraction. Additionally, existing user profile models use 2 dimensional (2D) and multi-dimensional (MD) approaches to relate user preferences to consumption history (Adomavicius et. al., 2005; Adomavicius & Kwon, 2007; Yu et. al., 2006). The difference between the two is that multi-dimensional approach uses multiple dimensions (User $\times$ Ratings $\times$ Contexts $\times$ Relevance) to relate user preferences and their consumption history, whereas a 2D approach uses only information about users and ratings (User $\times$ Ratings). Example of MD recommendation systems is presented by Gho et al. (2011) where location, device screens, network bandwidths, activity, mood, time, gender, language, etc., are used to deliver relevant multimedia contents to mobile users. A good example of 2D profiling approach is presented by Sarwar et. al. (2001), which uses only user information and item ratings to recommend items to users.

Unlike 2D-based user profiles that do not provide means to accommodate additional dimensions, such as contextual information, MD-based user profiling technique addresses this weakness. Nevertheless, current MD-based profiles rely on user ratings. In situations where ratings are not provided, this approach will suffer from poor recommendation quality. A solution that renders recommendations to mobile users with or without

ratings by incorporating contextual information into the user profile model is therefore desirable. Such profiles should be flexible enough to allow incorporation of contextual information into existing recommendation algorithms. We propose a contextual user profiling process to address the stated problems of existing user profile techniques. We have also proposed the extension of the traditional CBF, CF, and hybrid recommendation systems to produce context-aware CBF, context-aware CF and context-aware hybrid recommendation algorithms based on this new contextual user profile.

CONTEXT-AWARE MEDIA PERSONALIZATION FOR SMARTPHONE USERS

Assisting mobile users to make multimedia consumption choices is very crucial to the goal of anytime, anywhere information access. We designed MobCAMP by extending existing traditional personalized recommendation algorithms to suggest content, using contextual information. MobCAMP relies on a contextual user profile model, and a suit of context-aware recommendation services, namely collaborative, content and hybrid recommendations. The basic working concept of MobCAMP involves computing and tailoring personalized recommendations based on the contextual situations in which a target user or his friends have preferred certain content in the past. To achieve this, MobCAMP implements some basic components namely, context recognition model, contextual user profile model, multimedia profiling and context-aware recommendation algorithms.

Context Recognition

To capture contexts dynamically without asking users to manually provide them, we built a context recognition process (Otebolaku & Andrade, 2016), which can be ported on smartphones running so-

phisticated operating systems, such as Android. The recognition process uses events from the smartphone built-in sensors, such as accelerometer, orientation, and rotation sensors (to recognize user movement), GPS/WiFi (to recognize the user location), and the device clock (to capture time information). Generally, data produced by these sensors are low-level events that cannot be used directly by practical mobile applications (Kwapisz et. al., 2010). Therefore, MobCAMP relies on the context recognition process on mobile user's device to infer *high-level contexts* from sensor's low-level data. This process is achieved in four phases, which are smartphone sensor data capturing, data preprocessing, model building and context classification. In the data capturing phase, labeled high-level contexts such as user's activities [Walking, Sitting, Jogging, Driving, Running, etc.], including points of interest (POI) location information were collected using a mobile application running on the smartphone. The application collected 128 samples of data from each sensor's 3 axes, in continuous 3 seconds, with 64 samples from the previous 3 seconds overlapping the next 3 seconds. In the data preprocessing phase, outliers were removed (Lau and David, 2010). This is achieved by removing erroneous data segments from the beginning and ending of each collected data sample to minimize the influence of noise in the data. Simple time series features [range, mean and standard deviation] were then extracted from the remaining data samples.

In the model building and classification phases, extracted features in the last process is fed into a set of classification algorithms (Maninni, 2010) to build the context recognition models, which classify the features into activities and their corresponding locations, using leave-one-subject-out validation approach (Otebolaku & Andrade, 2013).

Contextual User Modeling and Profiling

The goal of user modeling or profiling is to capture not only interests or preferences of users but also

information about those things they do not like or want in specific contexts using either implicit or explicit processes (Otebolaku and Andrade, 2014a). We designed a dynamic and generic contextual user profile model, which summarizes user's content consumptions into a limited set of categories (Otebolaku and Andrade, 2014b). Categories are characterized by one or more genres, and genre is characterized by a number of properties. Additionally, it incorporates contextual dimension, associating one or more inferred contexts with each category-genre-property concept. We modeled the user profile as a four-level tree. The root of the tree is the user u_i with optional demographic information. The first level nodes correspond to category; the second level represents genre; the third level contains properties of a given category-genre. This level provides media item's context, characterizing at a finer detail, the consumed content and thus, user preferences. A limited set of properties is used for each genre to obtain a good compromise between sufficient degree of characterization of content and reasonable dimensions of the user profile. The leaf nodes provide information about contexts where user preferences are observed. Leaf nodes have three fields – type, weight, and lifetime, whereas all other nodes have only the type field. In the leaves, types represent the type of context. The weight provides information about number of times a user has consumed items of that *category-genre-property* in specific contexts, whereas lifetime defines the last time the user has consumed an item in a category. Each time the user starts consuming multimedia content, the system generates a contextual user profile vector V_c from the overall contextual user profile. After acquiring context data from the smartphone's sensors and inferring the current contextual situation of the user, the system uses this inferred data to filter the user profile based on context pre-filtering method (Adomavicius et al., 2005). Value of the recognized current context of use is compared with the leaves of the profile (context nodes) to identify the upper nodes that provide values for computing elements of V_c .

The *contextual user profile* is an important part of MobCAMP, which seamlessly integrates other components of the system. It also keeps track of the smartphone user's consumption history and contexts. The contextual user profile is updated using two approaches, explicit and implicit relevance feedbacks (Pazzani & Billsus, 2007). The former grants users the ability to modify values assigned to their preferences by the system. The implicit approach involves preference learning without involving users directly, but by updating their profiles, using information about user's response to recommended items.

Media Content Profiling

In addition to the contextual user profiling, it is necessary to create a media profile, represented by a vector V_M , for each candidate media item. This vector contains terms representing content of each candidate multimedia item (Otebolaku and Andrade, 2015a). To describe media items, the proposed system relies on the availability of semantic metadata using the MPEG-7 MDS description tools (MPEG7, 2013). For each media item, a vector V_M is initially created as an exact replica of V_C . Then, for every element of V_M , the system inspects the MPEG-7 metadata for a match. If it finds a match, it retains the intensity (relevance) of the matching element in V_M . Otherwise, it assigns zero to the element. The intensity measures interest generated by the user profile based on the frequency of media item's consumption in context.

Context-Aware Personalized Recommendations and Adaptations

Classifications of multimedia items in specific contexts, which can be performed in three phases, rely on the contextual user profile model. We extended three algorithms, namely (1) context-aware content based process. (2) Context-aware collaborative filtering process. (3) Context-aware content based collaborative process (CACBCP).

However, we will only introduce the third process. One common factor in these processes, however, is the *contextual user profile* (CUP) that relates user preferences to infer user preferences in any given contextual situation. The context recognition model infers the contextual information. These context-aware processes were extended with flexibility to allow non-contextual versions to execute in situations when contextual information might not be available. This would allow the system to switch between contextual and non-contextual user profiles. CACBCP first classifies users and multimedia content they have consumed in contexts similar to the target user's present context. Subsequently, it identifies every user who is similar to the target user by searching through their contextual profiles, looking for contexts that match the target user's present context. For every profile with a match, the intensity of corresponding category-genre-property nodes in the target user's profile is retrieved to form a user-multimedia content matrix. This matrix is then used to generate the similarity between each user's profile and the target user profile, using Pearson Correlation. After this calculation, the top n most similar users are then selected in decreasing order of the generated similarity values. The first n users, who have consumed content in the same or similar contexts to the target user's current context, with the highest similarity values are the so-called friends or neighbors of the target user. In the second phase, candidate media items for each neighbor are ranked by obtaining vectors V_c and V_m of the contextual user profile of every neighbor and candidate media profile vectors respectively. By applying the cosine distance correlation, the distance between these vectors is then generated.

In the third phase, using the cosine distance, the prediction for each of the contents for the target user, is generated using the Resnick prediction (Resnick et. al., 1994). Recommendation set is built by ordering candidate media items in descending order of magnitude of the computed prediction values. CACBCP also tracks the user's consumption behavior to improve the system, by

updating the profile whenever the user consumes any kind of media item.

MobCAMP Implementation

The implementation of MobCAMP consists of three primary components. The context recognition module that runs on the user's smartphone, monitoring, learning, and predicting user's contexts. This module gathers events from smartphone built-in sensors, pre-processing them, and inferring user's higher-level contexts from those events. Recognized context is then sent to CUP. CUP manages the preferences of users, by relating them to the user's present and past contexts (if any). It also learns the user's content consumption preferences and updates the profile accordingly. It stores user's consumption history and preferences according to the contexts in the profile repository. The third component, the personalized recommendation service, implements among others, CACBCP and a media content profiling process. The latter obtains content metadata from the Web, crawling and extracting useful information, whereas the former ranks and recommends content to the target user according to her contexts and preferences, and those of her friends. The adaptation process uses the network and device constraints as well as media item metadata to tailor the selected content accordingly. The context recognition process and recommendation client were implemented as an Android process and an application running on Galaxy S I9000 smartphone. The context-aware personalized recommendation service, the CUP, and the media profile service were implemented using Java EE components and exposed as REST web services interfaces (JavaEE, 2015), which can be accessed by clients running on the smartphones via Wi-Fi. Experiments conducted to evaluate the feasibility and the efficacies of the system produced encouraging results. For example, evaluations of the system using contextual information and without using contextual information show that recommendations with contextual information produce more relevant suggestions.

FUTURE RESEARCH DIRECTIONS

In order to address the weaknesses of personalized recommendation systems, many researchers are exploring CARS (Otebolaku & Andrade 2015a; Adomavicius et. al., 2011; Su et. al., 2010; Adomavicius et. al., 2005; Chen, 2005; Vallet et. al., 2007; Yu et. al. 2006). Nevertheless, present context-aware personalized recommendation techniques rely on rating provided by users in certain contexts. In practice, mobile users do not always provide ratings and sometimes, they consider this as distractions. Another challenge is that it is computationally expensive to compute recommendations for users who have similar tastes as the current user, especially when millions or even billions of users are involved. Tracking consumption history and knowing with whom users interact also require expensive computations. Recently, however, adoption of social networks, such as Twitter, Facebook, Google+, YouTube, etc. is providing a new platform to deal with this problem (Konstas, 2009). Personalization of mobile content using contextual recommendations will benefit from real-time social network data analytics based on user profile information, such as the user's online relationships, connections between other users, multimedia content sharing, and social tagging. Using social networks and contextual information as sources of data for recommendation systems, the expensive computations required by current similarity measures, especially when huge numbers of users and items are involved, will be greatly reduced. What would be required are friends of users on social networks, since it is believed that people have direct connections only with their friends, forming a very strong social influence. In addition, using social contexts to understand what a user needs, when and how he/she needs it as well as social and personalized engagements are important factors that will drive next generations of personalized recommendations for mobile users with relevant, timely, context-sensitive personalized yet non-invasive content deliveries. This important area

will become the center of the next generation of context-aware personalized systems. But, using social context sources is a challenging process considering privacy and security issues. Many social network users feel unsafe to share their preferences, contexts e.g. locations, activities, etc. with third party applications.

Nonetheless, we believe that social network based contextual information will improve the efficacy of context-aware recommendation systems, particularly those developed for mobile users. Nevertheless, researchers must study the implications of building context-aware personalized systems based on contextual information gleaned from social networks. Problematic issues of trust, privacy, and security, which are very critical, require important attention. There have been disturbing concerns by users on the issues of trust, privacy, and security, which could expose users to grave dangers and fraud as their data might be exposed to mischievous third parties. Users need the assurance that they are safe, and that their privacy is adequately guaranteed.

CONCLUSION

Smartphones have become integral parts of our daily routines because of their portability, incredible appeals and ability to process myriad multimedia content. With smartphones, we are now moving from the era of user's online routines to the era where online has become parts of user's routines. We are continuously seeking content that not only satisfies our contextual interests but also satisfies how we consume such content. However, with the huge volume of online-based content and constantly changing user preferences, it is difficult for users to find interestingly tailored content based on their contextual preferences. In this chapter, we have proposed a context-aware personalization system utilizing recommendation algorithms to assist mobile users to access relevant and interesting media content anywhere, anytime. It is not enough to suggest content to users when

and where they need the content but it is also equally important to suggest such content such that it is customized to the preferences of the users. One of the key components of the proposed system is the contextual user profiling/modeling. The contextual user profile has a wide scope, and can serve more than one context-aware filtering process. We have explained how to extend one of these processes, using contextual information, with the contextual user profile model serving a central role. We also discussed the context-aware content based collaborative technique and described its possible implementation. MobCAMP shows how context can be explored to improve recommendation efficacies, helping to filter out preferences that are not relevant in the present context and using it to adapt user preferred content. We have also argued that the future of context-aware multimedia personalization lies in using social network data with contextual information to glean user preferences for real-time contextual personalized recommendations.

KEY TERMS AND DEFINITIONS

Context Recognition: Is a process that identifies user's real-time contextual situations from sensory data, using pattern recognition, signal processing and machine learning algorithms.

Context-Aware Personalized Collaborative Recommendation: Is a personalized recommendation technique that suggests items, using items that other users have consumed in contexts similar to the target user's context.

Context-Aware Personalized Content-Based Collaborative Recommendation: Is a personalized recommendation technique that provides new items to a target user, using items that other users who are similar to the target user have consumed in the contexts similar to the target user's present context, including (if any) items that the target user has consumed in similar contexts.

Context-Aware Personalized Content-Based Recommendation: Is a personalized recommendation technique that provides suggestions to users, using items that such users have consumed in the past in contexts similar to their present contexts.

Context-Aware Personalized Recommendation: Is a technology that assists users to select

from overwhelming set of potential choices by matching and customizing available services to user's context dependent preferences. It supports the user by providing the right services in the right format at the right moments in order to improve user's experience.

Contextual User Profile: In context-aware personalized recommendations, a contextual user profile contains user's multimedia consumption preferences/interests in relation to contextual information such as location, optional personal information, user's device characteristics, and network information.

Smartphone: Is a mobile phone with sophisticated processing and computing capabilities, running an advanced operating system such as Android, Windows mobile, IOS, etc.

Smartphone Built-in Sensors: These are sensors including accelerometers, gyroscopes, GPSs, Wi-Fi, proximity sensors, etc. embedded in commercial smartphones.

Target User: Is a user whose profile is currently being processed by the recommendation system. It can also be considered as a user to whom recommendations are being provided.

Design of Compensators for Comb Decimation Filters

M

Gordana Jovanovic Dolecek
Institute INAOE Puebla, Mexico

INTRODUCTION

Decimation is the process of decreasing the sampling rate by an integer, called decimation factor. Decimation has applications in communications, audio signal processing, Sigma Delta Analog to Digital converters, among others. In order to prevent aliasing (unwanted replicas of the input signal), the signal must be previously filtered by a low pass filter, called decimation filter (Jovanovic Dolecek, 2003). The comb filter is the simplest decimation filter usually used in the first decimation stage (Hogenauer, 1981). This filter does not require multipliers, because all its coefficients are equal to unity. In order to achieve correct performance, the comb decimation filter should have a flat pass band of interest. However, comb magnitude characteristic has a droop in the pass band of interest which may deteriorate the decimated signal. The solution is to compensate for a comb pass band droop by an additional simple filter, called compensator. Different methods are proposed for compensator designs. The objective of this paper is to categorize and describe the most important methods, proposed so far, and to propose some future direction for the compensator designs.

BACKGROUND

The transfer function of comb filter is given by the following equation:

$$H(z) = \left[\frac{1}{M} \frac{1 - z^{-M}}{1 - z^{-1}} \right]^K \quad (1)$$

where M is the decimation factor and K is the order of the filter.

The magnitude response of the filter is given as:

$$|H(e^{j\omega})| = \left| \frac{1}{M} \frac{\sin(\omega M / 2)}{\sin(\omega / 2)} \right|^K \quad (2)$$

The comb pass band is defined by the pass band edge (Kwentus & Willson, 1997):

$$\omega_p = \pi / RM \quad (3)$$

where R is the decimation factor of the stage that follows the comb decimation stage.

For values $R < 4$, the pass band is considered as a wideband, and in an opposite case it is a narrowband.

As an example, Figure 1 shows the wide pass band zoom ($R=2$), of the magnitude response of comb filter with the decimation factor $M=12$ and an order equal to $K=3$. Note that the response is not flat and has a droop, which increases with the increase of the frequency ω . The inverse comb magnitude characteristic:

$$|H_i(e^{j\omega})| = \left| \frac{1}{H(e^{j\omega})} \right| = \left| \frac{M \sin(\omega / 2)}{\sin(\omega M / 2)} \right|^K \quad (4)$$

is also shown.

The product of the magnitude characteristics (2) and (4) results in unity:

$$|H(e^{j\omega})| |H_i(e^{j\omega})| = 1 \quad (5)$$

Figure 1. Magnitude and inverse magnitude characteristics of comb, $M=15$, $K=3$, $R=2$

Consequently, in order to get a flat comb magnitude characteristic it is necessary to cascade comb with a filter which has magnitude characteristic approximately equal to the inverse comb magnitude characteristic in the pass band. This filter is called a compensation filter. Denoting the magnitude characteristic of compensator as $|G(e^{j\omega})|$ it follows:

$$|G(e^{j\omega})| \approx |H_i(e^{j\omega})|, \text{ for } 0 \leq \omega \leq \omega_p \quad (6)$$

where ω_p is the pass band edge defined in (3).

Usually, compensation filter works at a low rate, i.e. after decimation. As a consequence, at high input rate, compensator is expanded by M .

The compensated comb is the cascade of comb and compensator. The corresponding transfer function at high input rate is:

$$H_{comp}(z) = H(z)G(z^M) \quad (7)$$

There are two principal reasons why an inverse comb filter cannot be a compensator: 1) Comb filter has zeros on the unit circle, becoming poles in the inverse comb filter, thus resulting in instability. 2) The resulting magnitude characteristic is equal unity for all frequencies. However, the unity magnitude characteristic is only required for the pass band.

Consequently, compensator should be designed to approximate inverse comb magnitude characteristic only in the pass band, and to no deteriorate comb stop band characteristic. Additionally, knowing that a comb filter is a very simple multiplier less filter, its compensator should be also a simple and desirable multiplier less filter.

REVIEW OF METHODS FOR DESIGN OF COMB COMPENSATORS

Different methods for design of comb compensators are advanced in the literature. The com-

Figure 2. Pass bands of comb, minimum error function-based compensator and compensated comb

compensator filters are usually FIR (Finite Impulse Response) filters due that FIR filters are always stable and can be designed to have a linear phase. The methods can be divided into two main groups: Methods requiring multipliers and Methods with multiplier less designs.

Methods Requiring Multipliers

1. **Minimum Error Function Method (Kim, Lee, Alm, & Choi, 2006):** The wideband compensator at low rate is defined by the following second order transfer function:

$$G(z) = \frac{-a}{(1-2a) + 1/(1-2a)z^{-1}} \quad (8)$$

where a is parameter obtained by minimizing the error function for a given M and K . Taking into account the filter symmetry, total two multipliers

are required. The authors provide the values of the parameter a , obtained by minimizing the error function for values for $M=2$ to 17 and $K=5$. As an example Figure 2 shows the pass bands of the original comb, compensator, and the compensated comb taking $M=17$, and $K=5$ ($a=0.1805$). The pass band is defined in (3) taking $R=2$.

2. **Maximally Flat Error Criterion Method (Molnar & Vucic, 2011):** Wideband compensator is designed as a linear-phase FIR filter that approximates the response in (4) in a maximally flat sense. The compensator's coefficients (up to 18 coefficients) are obtained by solving a linear system of equations, depending on values of M and K . As an example, taking $M=30$ and $K=4$, the transfer function of the designed filter is obtained as:

$$G(z) = 0.0008z^{-1} - 0.0112z^{-2}$$

Figure 3. Pass bands of comb, maximally flat compensator and compensated comb

$$\begin{aligned}
 &+0.0800z^{-3}-0.3987z^{-4}+1.6582z^{-5} \\
 &-0.3987z^{-6}+0.0800z^{-7}-0.0112z^{-8} \\
 &+0008z^{-9}
 \end{aligned} \quad (9)$$

The compensator requires five multipliers and eight adders. The pass band zoom of the compensator magnitude characteristic is shown in Figure 3. The zooms of the pass band magnitude characteristics of comb and compensated comb are also shown. As a result of maximally flat design, the compensated comb has a flat magnitude characteristic especially in the lower part of the pass band, as can be seen in Figure 3.

A similar approach, based on maximally flat design, is proposed in (Fernandez-Vazquez & Jovanovic Dolecek, 2012), that includes also a multiplier less design.

Multiplier Less Methods

3. **Sinusoidal Magnitude Response Method (Jovanovic Dolecek & Mitra, 2008):** Second order narrowband compensation filter has the following transfer function:

$$G(z) = -2^{-(b+2)} \left[1 - (2^{b+2} + 2)z^{-1} + z^{-2} \right] \quad (10)$$

where b is a parameter that depends on the comb parameter K . One can observe that the compensator does not depend on the decimation factor M .

The values of parameter b are: 2 for $K=2$, and 3; 1 for $K=4$; and 0 for $K=5$ and 6, taking $R=8$ in (3). The magnitude characteristic is in the sinusoidal form:

$$\left| G(e^{j\omega}) \right| = 1 + 2^{-b} \sin^2(\omega M / 2) \quad (11)$$

Figure 4. Pass bands of comb, narrowband compensator and compensated comb

As an example, using $M=14$, $K=3$, ($b=2$), Figure 4 shows the pass bands of comb, sinusoidal magnitude response compensator, and the compensated comb.

4. **Minimum Squared Error Method (Jovanovic Dolecek, 2009):** The wideband compensator, ($R=2$) proposed in (Jovanovic Dolecek, 2009) has the following transfer function:

$$G(z) = [G_1]^{K_1} \quad (12)$$

where:

$$G_1(z) = -2^{-4} [z^{-1} - (2^4 + 2)z^{-2} + z^{-3}] \quad (13)$$

$$K_1 = \begin{cases} K & \text{for } 1 < K \leq 3 \\ K-1 & \text{for } K > 3 \end{cases} \quad (14)$$

The coefficients of the filter (13) are obtained using the condition that the compensator magnitude characteristic has the value 1 for $\omega=0$ and minimizing the squared error between the inverse comb characteristic and the compensator, in the pass band. Finally, the obtained coefficients are rounded using the rounding constant $r=2^{-6}$. The only parameter of design is the parameter K_1 , which depends only on the parameter K of the comb filter, as shown in (14). Note that filter (13) remains the same for all values of comb parameters M and K (see Figure 5).

5. **Min Max Absolute Error Function Method (Jovanovic Dolecek & Dolecek, 2010):** This method has a goal to decrease maximum absolute value of the pass band deviation in comparison with the method proposed in (Jovanovic Dolecek, 2009), and in same time decrease the number of the required adders. To this end, the proposed filter has the following transfer function:

Figure 5. Pass bands of comb, wideband minimum squared error compensator and compensated comb

$$G(z) = S \left[Bz^{-1} + Az^{-2} + Bz^{-3} \right] \quad (15)$$

where the parameters S , B , and A depend on the value of comb parameter K , and are obtained by minimizing the maximum absolute error function. The corresponding values are shown in Table 1.

Figure 6 shows the magnitude responses in the pass band, for $M=16$ and $K=4$, for comb, min max absolute error compensator, and compensated comb.

Table 1. Design parameters of min max-based compensator

K	S	B	A
1	2^{-4}	-1	2^4+2^1
2	2^{-3}	-1	2^3+2^1
3	2^{-4}	$-2 \cdot 2^0$	$2^4+2^2+2^1$
4	2^{-2}	-1	2^2+2^1
5	2^{-4}	$-2^2 \cdot 2^0$	$2^4+2^3+2^1$

6. **Interval Analysis Based Method (Pecotic, Molnar & Vucic, 2012):** The compensator's coefficients are obtained by optimization technique based on the interval analysis, and are expressed as the sums of powers of two (SPT), thus resulting in a multiplier less design. The filter coefficients in SPT forms are provided in a Table in terms of the values of K and the defined number of the compensator coefficients. The advantage of this method is that it provides the filter's coefficients not only for different values of K but also for different compensator orders. As an example, the decimation factor $M=32$ and $K=5$ are considered. In order to demonstrate the flexibility of the design two cases are elaborated, depending on the desired number of the filter coefficients.

In the first case the order of the filter is three, requiring 7 adders:

Figure 6. Pass bands of comb, wideband min max compensator and compensated comb

$$G(z) = g_0 + g_1 z^{-1} + g_2 z^{-2} \quad (16)$$

where:

$$\begin{aligned} g_0 &= g_2 = -2^{-2} - 2^{-4} - 2^{-6}; \\ g_1 &= 1 + 2^{-1} - 2^{-3} + 2^{-7} \end{aligned} \quad (17)$$

Figure 7 shows the pass bands of comb, interval analysis-based compensator, and compensated comb.

In the second case the compensator order is five and the filter has 14 adders:

$$G(z) = g_0 + g_1 z^{-1} + g_2 z^{-2} + g_3 z^{-3} + g_4 z^{-4} \quad (18)$$

where:

$$\begin{aligned} g_0 &= g_4 = 2^{-3} - 2^{-5} - 2^{-7} + 2^{-10}; \\ g_1 &= g_3 = -2^{-1} - 2^{-6} + 2^{-9} - 2^{-11}; \\ g_2 &= 2^{-3} - 2^{-5} - 2^{-7} + 2^{-10} \end{aligned} \quad (19)$$

Figure 8 illustrates the pass bands of comb, compensator and compensated filter.

As expected, compensator in the second case provides better comb compensation, due to its higher complexity.

7. Trigonometric Approach Method (Jovanovic Dolecek & Fernandez-Vazquez, 2014): The method is based on the sine-squared magnitude response:

$$|G(e^{j\omega})| = 1 + B \sin^2(\omega M / 2) \quad (20)$$

Table 2. Parameters of trigonometric-based compensator

The Values of Comb Parameter K	The Values of Compensator Parameter B
1	2^{-2}
2	2^{-1}
3	$2^{-1} + 2^{-2}$
4	2^0
5	$2^0 + 2^{-2}$

Figure 7. Pass bands of comb, interval analysis based-compensator (three coefficients), and compensated comb

Figure 8. Pass bands of comb, interval analysis based-compensator (five coefficients), and compensated comb

where the values of compensator parameter B depend on the values of K , as shown in Table 2.

The filter has a low complexity requiring 3 adders for $K=1, 2, 4$ and 4 adders for $K=3$, and 5. As an example Figure 9 shows the magnitude responses in the pass band for the comb, compensation filter, and compensated comb, taking $M=18$ and $K=4$. (The parameter $B=2^0$).

8. **Amplitude Transformation Method (Troncoso Romero & Jovanovic Dolecek, 2013):** The method is based on the amplitude transformation of the cosine squared magnitude characteristic. The filter has low complexity, requiring only 4 adders. The filter coefficients in terms of K are obtained from the provided formula. As an example considering $M=25$ and $K=5$ the transfer function of the compensator is given as:

$$G(z) = (1 + 2^{-2})[2^{-2} + z^{-1}(1 - 2^{-1}) + z^{-2}2^{-2}] \quad (21)$$

Figure 10 shows the magnitude characteristics in the wide pass band ($R=2$) for comb, amplitude transformation-based compensator and the compensated comb.

9. **Two-Adders Method (Romero Troncoso, Molina Salgado & Jovanovic Dolecek, 2015):** The compensator proposed in (Romero Troncoso, Molina Salgado & Jovanovic Dolecek, 2015) is the simplest compensator requiring only two adders. The transfer function is given as:

$$G(z) = 1 + 2^{d-2} - 2^{d-2} z^{-1} \quad (22)$$

where d is an integer which depends on K .

The values for the parameter d are given for both: narrowband and wideband compensation. For a narrowband compensation the values of d are equal to -1 and 0 for the values of K equal to 2, 3, and 4, 5 respectively. Similarly, for a wideband case, $d=0$ for K equal to 2, and 3; $d=1$, for $K=4$, and 5. This filter requires only two adders and does

Figure 9. Pass bands of comb, trigonometric-based compensator, and compensated comb

Figure 10. Pass bands of comb, amplitude transformation -based compensator, and compensated comb

not have the symmetry and consequently its phase is not linear. However, the phase is approximately linear in the pass band. As an example consider $M=10, K=4$ and narrowband compensation ($R=8$), taking $d=0$. Figure 11 shows the magnitude responses of comb, two adders based-compensator and compensated comb.

Next, the wideband case is considered taking the value of $d=1$. Figure 11 shows the corresponding magnitude responses.

It can be observed that the narrowband compensation is better than the wideband compensation. Another interest feature of this filter is that it has zero inside of unit circle. Knowing that the comb filter has all zeros on the unit circle, the compensated comb is practically a minimum-phase filter thus having a low group delay.

10. **Sharpening-Based Method (Jovanovic Dolecek & Harris):** The narrowband filter given in (10) is sharpened using the simplest sharpening polynomial $H_{sh}=2H-H^2$:

$$G(z) = 2H_c(z) - [H_c(z)]^2 \quad (23)$$

where:

$$H_c(z) = -2^{-(b+2)} [1 - (2^{b+2} + 2)z^{-1} + z^{-2}] H(z) \quad (24)$$

and the parameter b is given in (Jovanovic Dolecek & Mitra, 2008). In spite that the compensation filter from (Jovanovic Dolecek & Mitra, 2008) is a narrowband filter, using the sharpening, the wideband compensation is obtained, as shown in the following example.

As an example, consider $M=11$ and $K=2$. The parameter b is equal to 1, leading to the following transfer function:

$$\begin{aligned} H_c(z) &= -2^{-3} [1 - (2^3 + 2)z^{-1} + z^{-2}] \left[\frac{1}{11} \frac{1 - z^{-11}}{1 - z^{-1}} \right]^2 \\ &= -2^{-3} [1 - (2^3 + 2)z^{-1} + z^{-2}] \left[\frac{1}{11} \frac{1 - z^{-11}}{1 - z^{-1}} \right]^2 \end{aligned} \quad (25)$$

Figure 11. Pass bands of comb, two adders narrowband compensator, and compensated comb

Figure 12. Pass bands of comb, two adders wideband compensator, and compensated comb

Figure 13. Pass bands of comb and sharpened narrowband compensator

Figure 13 shows the pass bands of comb and the filter from (25). Note that there is perfect wideband compensation. However, the price is the increased complexity and deterioration of comb alias rejection.

FUTURE RESEARCH DIRECTIONS

The number of methods for comb pass band compensation is proposed so far. Some promising characteristics of the proposed compensators are for example multiplier less design, work at low rate, independency of the decimation factor, easy design. However, considering the future development of modern information technology and new designs of oversampled sigma delta modulators and software defined radio, where comb filters have important applications, the future trends are in the low power multiplier less designs, and reconfigurability. Additionally, knowing that the multiplier less compensators proposed so far

still have an absolute value of pass band deviation which is about 3 dBs, in future designs it is expected to decrease the maximum absolute value of the pass band deviation, and thus provide approximately flat pass band characteristic of the decimated comb, without a significant increase of filter complexity expressed in the number of adders, and without deterioration of a comb aliasing rejection capability.

Knowing that there are a number of methods, proposed so far, for improving a comb alias rejection, one possible direction is to investigate efficient compensator designs for modified combs with an improved alias rejection.

CONCLUSION

This article presents review of the methods for comb compensators designs. The simplest decimation filter is a comb filter. However, its magnitude characteristic in the pass band is not flat and has

a pass band droop, which may deteriorate a decimated signal. Therefore, it is important to improve a comb pass band magnitude characteristic with a simple filter, called compensator. Knowing that a comb filter is a very simple multiplier less filter, its compensator should be also a simple filter.

The compensators usually work at low rate, and do not depend on the decimation factor but only on the comb order K . All methods can be divided into two main groups, depending if need multipliers or not. Usually, better compensation is obtained with more complex compensators including multipliers and/or an increased number of adders. The methods may be also classified as methods for narrowband and wideband compensation. Some of proposed methods can be used for both: narrowband and wideband compensation, just changing the design parameters.

KEY TERMS AND DEFINITIONS

Comb Filter: A simplest decimation filter which has all coefficients equal to unity.

Comb Compensation Filter (Compensator): The filter which has the magnitude characteristic which is an approximation of the inverse comb magnitude characteristic in the pass band. The filter is cascaded with the comb filter.

Comb Passband: The frequency band in which the decimated signal must be preserved. Ideally its characteristic is inverse of that of comb, thus resulting in approximately flat magnitude characteristic of the compensated comb in the pass band. The width of the pass band depends on the comb decimation factor, and the decimation factor of the stage which follows the comb decimation stage.

Decimation: Decreasing the sampling rate in a digital form by an integer.

Error Function: The difference of the desired and designed magnitude responses of compensated filter.

Multipliers: Implementation of coefficients of filter transfer function which cannot be presented as a power of two.

Multiplierless Design: The coefficients of filter are presented as powers of two which can be implemented as shifts and adders, thus avoiding multipliers.

An Empirical Study of Mobile/Handheld App Development Using Android Platforms

M**Wen-Chen Hu***University of North Dakota, USA***Naima Kaabouch***University of North Dakota, USA***Hung-Jen Yang***National Kaohsiung Normal University, Taiwan*

INTRODUCTION

When Apple launched its iPhones in 2007, they opened an App Store subsequently. They claimed the store has over 100 billion apps download, and has paid out more than \$30 billion to developers since its inception. There were more than 1.5 million apps available in 2015 (TechCrunch, 2015). The highly popular iPhones help the sales and development of applications. On the other hand, the large number of apps helps the sales of iPhones too. It is a win-win situation for both of the Apple, Inc. and app developers. Witnessing the success of the App Store, other mobile operating system providers realized they might be left behind if they did not have this kind of stores for their operating systems. They set up their own app stores immediately. Some of the major stores are given in Table 1 (Hu, 2016). The highly popular apps create great opportunities for IT companies and workers. However, traditional desktop programmers have problems switching to handheld programming because it requires a different approach from desktop programming (Kiely, 2001). This chapter introduces essential technologies for mobile/handheld computing, so more IT workers can join the mobile trend of computing.

Desktop application developers use standard tools or software (such as C++ and Java compil-

ers) to develop applications for different platforms (like Linux and Windows) with little or no changes. Unlike desktop application development, there are no widely accepted tools or software for mobile app development. For example, completely different approaches are required for Android and iOS app development. At the same time, mobile app development is much more complicated and platform-specific compared to desktop application development. This chapter introduces mobile app development by giving a simple Android application. Mobile developers can get a sense of mobile app development by reading this chapter and apply it to other platforms or further explore the Android app development.

The rest of this chapter is organized as follows. Section 2 gives background information about mobile/handheld computing, which includes a generic system structure of mobile handheld devices and client-side handheld computing. A variety of approaches is available for mobile app development. Sections 3 and 4 introduce the development using Android. Related tools and software for Android app development are introduced in Section 3. Section 4 explains a simple app development using Android. The example includes several XML and Java files and the Android Studio IDE (Integrated Development Environment) is used in the development. The final section summarizes this study.

Table 1. Major mobile application stores (Hu, 2016)

Company		Mobile Application Store		
Name	Major Mobile Products	Name	Major Operating Systems Supported	Launch Date
Apple Inc.	Smartphone Mobile operating system	App Store	iOS	07/10/2008
Open Handset Alliance (Alphabet)	Mobile operating system	Google Play	Android	10/22/2008
Microsoft	Mobile operating system	Windows Phone Apps	Windows Phone	10/06/2009
Research In Motion	Smartphone Mobile operating system	BlackBerry World	BlackBerry OS	04/01/2009

Opera	Mobile browser	Opera Mobile Store	Almost all	02/16/2009
Sony	Smartphone	Apps	Android Windows Phone	02/xx/2004

BACKGROUND

Handheld computing is the use of handheld devices like smart cellular phones to perform wireless, mobile, handheld operations such as browsing the mobile Web and finding the nearby gas stations. This section discusses two handheld computing subjects: mobile handheld devices and client-side handheld computing.

Mobile Handheld Devices

Mobile users perform mobile transactions using small wireless Internet-enabled devices, which come with several aliases such as handhelds, palms, PDAs, pocket PCs, and smartphones. To avoid any ambiguity, a general term, mobile handheld devices, is used in this article. Mobile handheld devices are small general-purpose, programmable, battery-powered computers, but they are different from desktop PCs, notebooks, or tablets due to the following two special features: small screen/body size and mobility.

Short battery life and limited network bandwidth, memory, processing power, and functional-

ity are additional features, but these problems are gradually being solved as the technologies improve and new methods are constantly being introduced. Though the Wi-Fi and 4G networks and above go some way toward addressing the problem of limited bandwidth, the wireless bandwidth is always far below the bandwidth of wired networks. The small screen/body size restricts the input speed and convenience. Figure 1 shows a typical system structure for handheld devices, which includes the following six major components (Hu, Zuo, Chen, & Yang, 2010):

- **Mobile Operating Systems:** Simply adapting desktop operating systems for handheld devices has proved to be futile. A mobile operating system needs a completely new architecture and different features to provide adequate services for handheld devices. A generalized mobile operating system structure can be visualized as a six-layer stack: (i) applications, (ii) GUI, (iii) API framework, (iv) multimedia, communication infrastructure, and security, (v) com-

Figure 1. A system structure of mobile handheld devices

puter kernel, power management, and real-time kernel, and (vi) hardware controller.

- Mobile Central Processing Units:** Handheld devices are becoming more sophisticated and efficient every day and mobile users are demanding more functionality from their devices. To achieve this advanced functionality, in addition to the obvious feature, low cost, today's mobile processors must have the following features: (i) high performance, (ii) low power consumption, (iii) multimedia capability, and (iv) real-time capability. The cores and architectures designed by Cambridge-based ARM Holdings Ltd. have dominated the mobile CPU market.
- Microbrowsers:** Microbrowsers are miniaturized versions of desktop browsers such as Netscape Navigator and Microsoft Internet Explorer. They provide graphical user interfaces that allow mobile users to interact with mobile apps.
- Input/Output Components:** Various I/O devices have been adopted by mobile handheld devices. The only major output device is the screen, but there are several popular input devices, among them: soft keyboards and touch screens.

- Memory:** Three types of memory are usually employed by handheld devices: (i) RAM, (ii) ROM, and (iii) flash memory. Hard disks provide much more storage capacity, but are more fragile.
- Batteries:** At present, rechargeable Lithium Ion batteries are the most common batteries used by handheld devices. However, the life of this kind of battery is short and the technology will not significantly improve unless and until manufacturers begin to switch to fuel cells, which may not happen for at least several years.

Synchronization connects handheld devices to desktop computers, notebooks, or peripherals to transfer or synchronize data. Without needing serial cables, many handheld devices now use either an infrared (IR) port or Bluetooth technology to send information to other devices.

Client-Side Handheld Computing

There are two kinds of handheld computing: server and client-side handheld computing. Server-side handheld computing includes the design and development of handheld software such as PHP programs that reside on servers. Client-side hand-

Table 2. The most popular four mobile operating systems and their features

Mobile OS		Android	iOS	Windows Phone	BlackBerry OS

Mobile application store		Google Play	App Store	Windows Phone Apps - Microsoft Store	BlackBerry World

held computing is the programming for handheld devices and it does not need the supports from server-side programs. Typical applications created by client-side handheld computing include (i) address books, (ii) video games, (iii) note pads, and (iv) to-do list. Various environments/operating systems/languages are available for client-side handheld programming. Table 2 lists the most popular four mobile operating systems (Hu, 2016; Google, n.d.a; Research In Motion, n.d.; Apple, Inc., n.d.; Microsoft, n.d.).

Each mobile operating system applies a different approach to accomplishing the development of mobile applications. Figure 2 shows a generic development cycle applied by them. Handheld emulators instead of the handhelds themselves are used for the development because of the convenience reason. The next section gives an example of Android application development. From the example, readers can get a sense of mobile app development, which is complicated and difficult compared to desktop application development.

Figure 2. A generic client-side handheld computing development cycle

ANDROID APPLICATION DEVELOPMENT ENVIRONMENT

There are a variety of mobile platforms and each platform has its unique approach for mobile app development. It is not possible to cover all of them in this chapter. This chapter focuses Android, which is the most popular mobile platform nowadays. Android is a software stack for mobile devices such as smartphones and tablet PCs (Open Handset Alliance, n.d.). It was developed by the Open Handset Alliance, a consortium of 84 hardware, software, and telecommunication companies led by Google devoted to advancing open standards for mobile devices. Google purchased the initial developer of the software, Android Inc., in 2005. Android includes an operating system, middle-ware, and key applications. The Android SDK (Software Development Kit) provides the tools and APIs necessary for developing applications on the Android platform using the Java programming language. Android uses the Dalvik virtual machine with just-in-time compilation to run compiled Java code. Android Studio download (Google, n.d.b) provides everything you need to start developing apps for Android, including the software such as Android Studio IDE, Android SDK tools, Android 6.0 (Marshmallow) Platform, Android 6.0 emulator system image with Google APIs, Android virtual device, and Intel Hardware Accelerated Manager (HAXM). This section introduces major components of Android and the next section will give an example of using these components to develop a small app.

Android Studio

In the past, Android app development in Eclipse with ADT (Android Development Tools) was highly recommended. Eclipse is a software development environment comprising an integrated development environment (IDE) and an extensible plug-in system and ADT is a plugin for the Eclipse IDE. Together they provide an integrated environment in which to build Android applications. Since

2014, Android Studio became the primary IDE for native Android application development. It is freely available under the Apache License 2.0. Android Studio is a powerful IDE and Figure 3 shows a screenshot of an instance of Android Studio, which includes the following major sections: Android logcat, component tree, Gradle console, (view) properties, project structure, and toolbar and tool buttons. Some of the features offered by Android Studio include Gradle-based build system, build variants and multiple apk (Android Application Package) file generation, code templates to help developers, layout editor with support for drag and drop theme editing, lint tools to catch problems, ProGuard and app-signing capabilities, and built-in support for Google Cloud Platform.

Android Virtual Devices (AVDs)

Mobile app development on the devices is not feasible because of many reasons such as the small size of devices and lack of powerful IDEs. In order to develop apps on desktop computers, a smartphone emulator is therefore needed. An AVD is an emulator that models an actual device by defining hardware and software options through AVD Manager:

- **A Hardware Profile:** Which defines the hardware features of the virtual device such as camera, network, emulated performance, and memory and storage,
- **A Mapping to a System Image:** Which defines what version of the Android platform will run on the virtual device such as the version of the standard Android platform and API level, and
- **Other Options:** Which specify the emulator skin you want to use with the AVD such as screen dimensions and resolution.

Figure 4 shows an instance of an AVD. Other than the AVD Manager, Android Device Monitor provides a graphical user interface for several Android application debugging and analysis tools.

Figure 3. A screenshot of an instance of Android Studio

Among many of its features, DDMS (Dalvik Debug Monitor Server), a debugging tool, provides port-forwarding services, screen capture on the device, thread and heap information on the device, logcat, process, and radio state information, incoming call and SMS spoofing, location data spoofing, and more.

SQLite, an Embedded RDBMS (Relational Database Management System)

Embeddable databases are embedded within devices or application processes. They include the following features making them fast and ideal for handheld devices: (i) removing the overhead associated with a client-server configuration, (ii) light weight in the sense that they require little memory during run time, and (iii) written in compact code. SQLite (n.d.a) is an open source embeddable RDBMS available on every Android device. SQLite includes the following major features: (i) supporting most of the SQL-

92 standard, (ii) running on all major operating systems, (iii) having support for the major computer languages, and (iv) including multitasked read operations and sequential writes. The SQLite structure (n.d.b) consists of four components: (i) SQL Compiler, (ii) Core, (iii) Backend, and (iv) accessories. It can store data up to two TB with each database saved in a single disk using a B⁺ tree data structure. SQLite supports the following datatypes: NULL, INTEGER, REAL, TEXT, and BLOB. The SQL statements are compiled into assembly code executed on the SQLite virtual machine, Virtual Database Engine (VDBE). An SQLite database is private to the Android app that creates it. To share data with other apps, Android provides Content Provider that uses standardized ways to retrieve and manipulate the stored data.

Google Play Services

Google Play (Store) is a digital distribution platform for the apps developed by using Android platform and published through Google.

Figure 4. An Android emulator displaying a driving direction between two locations

In order to use many services provided by the Google and Android, Google Play services is required for app development and uses. It is used to update Google apps and apps from Google Play. Google Play services provides core functionality like authentication, synchronization, and user privacy setting. It is an APK (Android application package), a package file format used by the Android operating system for distribution and installation of mobile apps and middleware. APK files, a type of archive file, can be installed on Android powered devices just like installing software on PC. Google Play services allows Android apps to easily integrate with Google services like Google Maps. Apps may not work if Google Play services is not installed.

A SIMPLE ANDROID APP EXAMPLE

This section gives an example of mobile app development using Android (Google, n.d.c). This application is based on the default template when an Android project is created. It has two different screens and is able to move from one

screen to another screen. Figure 5 shows the result screenshots. Two activities/pages are included in this application:

- HelloWorldActivity.java, which is the start-up page and
- NextPageActivity.java, which is the other page.

Other than the text, each of the pages contains a button, which is used to display the other page. The following five components of this app will be detailed next:

- *Android manifest file (AndroidManifest.xml)*, which is used to glue everything in the app,
- *Layout XML code (main.xml and next.xml)*, which defines the UI elements, their properties, and their arrangement, and
- *Java source code (HelloWorldActivity.java and NextPageActivity.java)*, which drives everything. It is this code that is ultimately converted to Dalvik executable and runs the application.

Figure 5. Two screenshots of the Android application

Android Manifest File

In its root directory, each Android application must have an AndroidManifest.xml file, whose main missions are to explain what the application consists of, what its major building blocks are, what permissions it requires, etc. It must declare the four components of an application:

- **Activity:** Which represents a single screen with a user interface,
- **Service:** Which runs in the background to perform long-running operations or to perform work for remote processes,

- **Content Provider:** Which manages a shared set of application data stored in the file system, SQLite database, or any persistent storage, and
- **Broadcast Receiver:** Which responds to system-wide broadcast announcements.

For example, if the application wants to access the Internet, this file must state that it would like to use the related permission, as presented in Box 1.

Layout XML Code

The user interface for activities is defined via layouts. The layout defines the UI (user interface)

Box 1.

Figure 6. A screenshot of a layout generated by Java code

elements, their properties, and their arrangement. There are two ways, Java code or XML, to define the Android app layouts. The Java code is usually for the dynamic layouts (i.e., the layouts are unknown when coding) and the XML is normally for the static layouts (i.e., the layouts are known in advance).

- **Java Code:** Java code is typically used to generate the layout when the content is unknown until runtime; e.g., if the layout depends on content which is read from the Internet. An example of this is the next three statements whose screenshot is shown in Figure 6:

```
TextView tv = new TextView(this);
tv.setText("Hello, Android");
setContentView(tv);
```

which compose the string “Hello, Android” and display it.

- **XML:** XML based layouts are defined via a resource file in the folder `/res/layout`. This file specifies the view groups, views, their relationship, and their attributes for a

specific layout. Defining layouts via XML is usually the preferred way as this separates the programming logic from the layout definition. For example, the following two layouts are used in this application:

- Home page at `res/layout/main.xml` and
- Next page at `res/layout/next.xml`

The application loads the screen specified in `main.xml` by the following Java command in the `HelloWorldActivity.java`:

```
setContentView(R.layout.main);
```

The following code, presented in Box 2, shows the contents of the file `main.xml`, one of the two screens of this application.

Java Source Code

The Java code is what drives everything. This application includes two screens/activities/classes:

- `HelloWorldActivity.java`, which is the main page, and

Box 2.

```
<?xml version="1.0" encoding="utf-8"?>
<LinearLayout xmlns:android="http://schemas.android.com/apk/res/android"
    android:orientation="vertical"
    android:layout_width="fill_parent"
    android:layout_height="fill_parent" ← Taking up all space
    android:gravity="center"
    android:background="@android:color/white">
    <TextView
        android:layout_width="fill_parent"
        android:layout_height="wrap_content" ← Expanding only far enough to contain the values
        android:gravity="center"
        android:text="@string/hello" ← The string "Hello, World!\n"
        android:textSize="25sp"
        android:textStyle="bold"
        android:textColor="@android:color/black"
    />
    <Button android:id="@+id/next" ← The button's ID being "next"
        android:layout_width="wrap_content"
        android:layout_height="wrap_content"
        android:textSize="15sp"
        android:text="@string/button"
    />
</LinearLayout>
```

- NextPageActivity.java, which is the other page.

These two screens are similar. Each of the screens displays text and a button. The button is used to activate the other activity/class, which displays the other screen. Notice that the class is based on the Activity class. An Activity is a single application entity that is used to perform actions. An activity is not required to have a user interface, but usually does. The onCreate method is called by the Android system when the Activity starts—it is where all initialization and UI setup should be performed. The OnClickListener is an interface definition for a callback to be invoked when a view is clicked and the onClick method is activated when the button on the application interface is clicked. The code presented in Box 3 shows the file HelloWorldActivity.java (the NextPageActivity.java has similar code):

FUTURE RESEARCH DIRECTIONS

This chapter gives an empirical study of mobile app development, which is more difficult compared to the development of desktop applications. However, mobile IDEs (integrated development environments) are revised and improved constantly. Though it may not come anytime soon, mobile IDEs may be as powerful and convenient as desktop IDEs one day. Before the day is coming, mobile developers are forced to use the mobile IDEs available to them. This chapter helps readers to get ready for mobile app development. The authors will keep updating this article based on the up-to-date mobile IDE technology from time to time. At the same time, the developers also have to pay attention to mobile IDE development, so they could incorporate the newest technology to their app development.

Box 3.

M

```

package com.example.helloworld;

import android.app.Activity;
import android.content.Intent;
import android.os.Bundle;
import android.view.View;
import android.widget.Button;

public class HelloWorldActivity extends Activity {
    /** Called when the activity is first created */
    @Override
    public void onCreate( Bundle savedInstanceState ) {
        super.onCreate( savedInstanceState );
        setContentView( R.layout.main ); ← Displaying the screen of main.xml

        final Button button = (Button) findViewById( R.id.next );
        button.setOnClickListener( new View.OnClickListener() {
            public void onClick( View v ) { ← Called when the button is clicked
                /** Here i calls a new screen. */
                Intent i = new Intent(
                    HelloWorldActivity.this, NextPageActivity.class );
                startActivity( i ); ← Launching the activity NextPageActivity
            }
        } );
    }
}

```

CONCLUSION

Mobile application stores (or app stores) sell or provide mobile applications/services for handheld devices such as smartphones and tablet computers. The applications/services are not necessarily from the storeowners. Many of them are from the third parties such as independent developers. A wide variety of mobile applications is available on the stores. Popular applications include mobile games, mobile offices, mobile shopping, and music. Additionally, mobile commerce is a coming milestone after electronic commerce blossoming in the late 1990's. However, it is also commonly admitted that the development in this field is constrained. There are some considerable barriers waiting to be overcome. One of the barriers is most software engineers are not familiar with handheld programming, which is the programming for handheld devices. This chapter explains the design and implementation of mobile apps by detailing the two subjects: handheld computing and Android

application. Client-side handheld computing is to use handheld devices to perform handheld operations, which do not need the supports of server-side computing. Various environments/languages are available for client-side handheld computing and programming. The rising and demise of mobile operating systems happen quickly and frequently and are hard to predict. Three current mobile operating systems likely to succeed are

- *Android*, the most popular mobile operating system nowadays,
- *iOS*, from the prestigious company Apple, and
- *Windows Phone*, from the software behemoth Microsoft.

They apply different approaches to accomplishing the development of handheld applications and it is almost impossible to predict which approaches will dominate the client-side handheld computing in the future, as the Windows to desktop PCs. Most

client-side handheld programming languages are a version of either C/C++ or Java. This chapter introduces the essential technologies for mobile/handheld app development and gives a simple example of Android application development. The given example shows handheld programming is complicated and difficult compared to desktop programming. Many developers thus try to stay away from client-side programming by switching to web apps (Shankland, 2012). However, this approach has the disadvantage of slowness and requires Internet accesses.

KEY TERMS AND DEFINITIONS

Android Studio IDE (Integrated Development Environment): Since 2014, Android Studio became the primary IDE for native Android application development. It is free software under the Apache License 2.0 developed by Google. It includes the following features: intelligent code editor, code templates and GitHub integration, multi-screen app development, virtual devices for all shapes and sizes, and Android builds evolved, with Gradle.

Android: It is a software stack for mobile devices that includes an operating system, middleware, and key applications such as contacts. It is a project proposed by the Open Handset Alliance, a group of more than 84 technology and mobile companies including Google, Inc.

Apps: A mobile app (or application) is a kind of software designed to run on mobile handheld devices such as smartphones. Examples of apps

are calendars, video games, and short message services (SMS).

Client-Side Handheld Programming: It is design and development of handheld/mobile software such as Android programs that reside on the handheld/mobile devices.

iOS (Previously iPhone OS): It is a mobile operating system developed by Apple Inc. for its mobile/handheld devices such as iPhone and iPad. iOS is derived from OS X (used for Apple's computers such as iMac and MacBook) and both are based on the Unix. It includes four abstraction layers: (i) the Core OS layer, (ii) the Core Services layer, (iii) the Media layer, and (iv) the Cocoa Touch layer. iOS includes a user interface interacted with multi-touch gestures such as swipe, tap, and pinch, all of which have specific definitions in iOS.

Mobile Handheld Devices: They are small general-purpose, programmable, battery-powered computers, but they are different from desk- or lap- top computers mainly due to the following special features: (i) limited network bandwidth, (ii) small screen/body size, and (iii) mobility.

Mobile/Handheld Computing: It is to use handheld devices such as smartphones to perform wireless, mobile, handheld operations such as managing personal data, playing video games, and browsing the Internet.

Server-Side Handheld Programming: It is design and development of handheld/mobile software such as CGI programs that reside on the servers.

Windows Phone: Windows Phone is a mobile operating system developed by Microsoft and is aimed at the consumer market. It is derived from Windows Mobile platform, which focuses on the enterprise market instead. Windows Phone includes a new user interface of flat, colored live tiles and a laterally scrolling canvas for accommodating more tiles.

Enhancing the Mobile User Experience Through Colored Contrasts

Jean-Éric Pelet

ESCE International Business School, France

Basma Taieb

University of Cergy Pontoise, France

INTRODUCTION

In 1940, during the Second World War, the Cambridge zoologist Hugh Cott published a textbook about camouflage, warning coloration and mimicry. He introduced the notion of disruptive coloration, which was defined as contingent on background matching, suggesting

the effect of a disruptive pattern is greatly strengthened when some of its components closely match the background, while others differ strongly from it. Under these conditions, by the contrast of some tones and the blending of others, certain portions of the object fade out completely while others stand out emphatically (p.50).

As stated by Schaefer & Stobbe (2006), disruptive coloration and background matching are both techniques of camouflage that are often quoted as textbook examples of natural selection. For example, the experiments conducted by Cuthill *et al.* (2005) illustrated that artificially colored moths, which had been designed to match their background of oak trunks in terms of color and brightness, survived better if they sported highly contrasting patterns on the edge of their wings compared to moths with the same patterns inside their wings. Furthermore, this phenomenon of contrast concerns all natural species in various fields and even human beings, such as soldiers in the army or surgeons in their operating room.

For example, military camouflage patterns were worn in the army to protect personnel and equipment from observation by enemy forces. Green uniforms, especially, and later other drab colors were used depending on the field of war (in Vietnam khaki green colored uniforms were favored, whereas in Irak khaki yellow was privileged). Surgeons operate in completely green or blue operating rooms to allow them to focus on what is red, namely blood and organs. This can be explained by the physiology of the human eye, notably the retina, which is lined with photoreceptor cells known as rods and cones. The rods are stimulated by dim light. In parallel, cones run “at full throttle” in normal brightness. Because human beings have three types of cones with different levels of sensitiveness to red, green and blue - red-sensitive cones are the most numerous, followed by the green-sensitive, and finally the blue-sensitive cones - the red color captures the surgeon’s attention more easily than the other colors. Thus, having an operating room with a dominant green or blue color allows a surgeon’s eyes to focus on the red color of blood and therefore on the surgery itself. The same question of contrast occurs on a webpage such as an e-commerce webpage, enabling users to read more or less easily, thanks to a properly chosen contrast ratio between the foreground and background colors.

“A frustrating experience on a website hurts my opinion of the brand overall” says Miller (2012). The author adds that many customers of

a brand are disappointed in the company itself if the mobile experience doesn't meet their expectations. The mobile experience or "*Mobile User Experience*" (MUE) refers to the perception users have of a mobile product or service, such as an app, a social media or a website, for example an e-commerce website. This perception mainly leans on the sense of sight. The principal variable among the viewable features of the Cascade Style Sheet (CSS) used to write formatting instructions (rules) for websites is color. Indeed most of the information available on a website comes from what is viewable: in fact, 80% of the information processed by an Internet user's brain results from sight (Mattelart, 1996), making color the main variable to take into account in research on consumer behavior when using a handled device for shopping purposes. Bearing in mind that the background color is the first factor to become apparent when the download of a webpage is in progress (Gorn *et al.*, 2004), thinking about colors to improve the MUE and leverage the benefits of companies is fundamental for the Return on Investment (ROI) of an organization. Nevertheless, attention given to the background color itself and the various parameters that summarize it (such as hue, brightness and saturation) is not sufficient to improve the customer experience. In order to answer this question, the present research compares the design cues of a m-commerce website on its color contrast occurred between foreground and background. An experimental design was developed to investigate the effects of m-commerce website design on emotions and behavioral intention within the context of smartphone usage.

This chapter therefore presents a literature review on the importance of the colored contrast of mobile website interfaces. The methodology section then presents the website built for the experiment, followed by results aiming at highlighting the behavioral intentions derived from the presentation of positive and negative colored contrasts. We conclude the paper with a discussion, some limitations and suggestions for future research, which give rise to some managerial implications.

BACKGROUND

Definition of the Mobile User Experience (MUE)

The term "mobile commerce" (m-commerce) was introduced in 1997 by Kevin Duffey at the Global Mobile Commerce Forum. According to Duffey's definition, m-commerce is an area separated from the e-commerce (electronic commerce) market, which is characterized by the carrying out of all operations by means of wireless devices, mainly smartphones and tablets (Shaikh & Gupta, 2014). M-commerce is specifically mobile-phone access to a wide spectrum of services covering finance (mobile banking), entertainment (music, movies, e-publications), and information and localization services (Pralat, 2013). Among mobile consumers, another action is increasingly practiced, namely "showrooming", where people use smartphones in traditional shops to search for information about the products on the Internet, compare prices and, in cases where they find an attractive offer, make their purchases online instead of at the shop (Pralat, 2013). The key to improving the MUE of e-commerce websites visited on a laptop/desktop interface seems to lie partly in the contrast that occurs between the background and foreground colors (Pelet, 2014). However, until now the effects of the colored contrasts occasioned by the foreground and background colors of the CSS of a website on consumer behavior have not been studied.

Total retail sales are increasing slowly but steadily in the USA according to e-Marketer (2015). Although sales are growing most quickly in the digital market, e-commerce is expected to rise only slightly as a share of the total, from 7.2% this year to 9.8% by 2019. Mobile still accounts for 1.6% of all retail, and by 2019 its share is expected to be 2.7%. According to Gentle (2015), current m-commerce figures indicate that a major shift is taking place, since the percentage of smartphone owners that use their phones to access the Internet was seen to double between

2009 and 2013, from 31 percent to 63 percent (Duggan and Smith, 2013). Gentle adds that in 2014, over 52 percent of e-retail traffic over four days, between Thanksgiving (Thursday, November 24, 2016) and Cyber Monday (Monday, November 28, 2016) was mobile (Siwicki, 2014). The editor underlines that current studies show that 67 percent of consumers say they are more likely to buy from a mobile-friendly site.

Customers are five times more likely to visit a competitor after having a frustrating mobile experience (Gentle, 2015). Consumers will more readily buy online when the website meets their mobile needs. 'Mobile needs' refers to the optimization of the page user's view on their mobile screen. This is called the "landing page" and its main function lies in optimizing the content of a website for any screen size, from watches and huge TV screens, to the screens on mobiles and tablets. For web designers or those in charge of digital content, optimizing the landing page therefore means relying on certain practices. Not respecting these guidelines can work against the brand. When a website fails to follow the guidelines from key industry players such as Google, it is penalized in several areas, for instance SEO (Search Engine Optimization) and it may subsequently not appear on the first page of major search engines. Users may stay longer thanks to the ease-of-use of a website, making them more likely to buy a product or use a service. They might also quit if they do not see what they are looking for right away on the website. Users therefore quit a website for ease-of-use reasons; and this is why the mobile-friendly aspect of its interface remains a key issue in retaining users for as long as possible. It is also a reason why three quarters of respondents said they are more likely to revisit a mobile-friendly website, in a survey managed by Google (2011). A mobile-friendly site encompasses several aspects to go beyond simply what the landing page promises, by taking into account content and layout that are compatible with various devices and screens

of all sizes. This is all about "responsive design", and includes touch, gesture and voice activation controls. The biggest changes that have occurred between laptop and desktop screens and mobile devices include the exploitation of another sense in addition to sight and hearing, namely touch. However, this sense is activated through visual data, since users touch the screen depending on what they see or read on the webpage.

Reading on the screen of a smartphone in the street can sometimes prove to be extremely challenging, especially when the sun shines, and when legibility conditions are not very good. Brands that do not pay attention to the readability of the content of their m-commerce (mobile commerce) website may lose consumers' intentions to buy and revisit as well as their intentions to recommend the website. In this respect, the contrast ratio created by the foreground (text) and background colors of the website needs to be carefully designed. As already mentioned by Pelet (2014) regarding e-commerce, the color contrasts of a website enhance the memorization of information and the intention to purchase (Pelet & Papadopoulou, 2010, 2012). Especially in the context of web design, color serves as a supportive medium for the layout of information. Hence, it works as a contrasting base. Reading time is shorter when there is good contrast. Some studies show that a positive contrast obtained with a light text over a dark background provokes online visitors to abandon a website and puts users in a negative mood (Pelet, 2010). A positive contrast inflicts a visual strain accompanied by eye fatigue, contrary to a negative contrast (a dark text over a light background). This is why we choose to distinguish the background and foreground colors in the experiment we present below by using both negative and positive contrasts to conduct our measurements. The positive contrast is yellow on green, and the negative one green on yellow, following Hill & Scharff's (1997) and Pelet & Papadopoulou's (2012) findings.

Controlling the Contrast Ratio of a Mobile Website's Interface

The legibility of the content is of paramount importance for MUE. By increasing the color contrast when designing websites, the readability and legibility of the information presented are improved, which directly correlates with the information that is absorbed and retained by consumers (Chadwick-Dias *et al.*, 2007; Gao *et al.*, 2011; Pelet and Papadopoulou, 2012). Researchers have already worked on the contrast of web interfaces (see for example Scharff & Ahumada, 2002: authors offer measures that predict the effects of background contrast variations on text readability; July 2003: authors measured text readability for positive and negative contrast text on a plain background at two contrast levels, 30% and 45%; 2003: authors show that letter identification performance is better for negative contrast (black text on gray background) than positive contrast (white text on gray background); 2003a: authors found that word identification and word discriminability was affected by the backgrounds in the same way that the paragraph search performance was affected, but that letter identifiability on these two backgrounds was predicted by the metric. They have also found a significant improvement from including different contrast gains for positive and negative contrasts in the metric. Unfortunately, word readability is not necessarily simply related to letter identifiability and simple contrast measures according to authors; 2003b; 2005: authors measured text legibility for light text and dark text. For paragraph readability and letter identification, responses to light text were slower and less accurate for a given contrast.; 2008; 2009; Ahumada, Scharff & Watson, 2006; Scharff, Ahumada & Hill, 1999; Scharff, Hill and Ahumada, 2000; Zuffi *et al.*, 2006; 2007: authors confirm previous works and find that letter identification latencies are predicted by an asymmetric contrast metric). None of these research projects relate to mobility and external environment conditions, which affect the contrast of the screen.

Legibility is the degree to which glyphs (individual characters) in the text are understandable or recognizable, based on appearance. The legibility of a typeface is related to the characteristics inherent in its design, which relate to the ability to distinguish one letter from another. Readability is the ease with which text can be read and understood. It is influenced by line length, primary and secondary leading, justification, typestyle, kerning, tracking, point size, etc. Thus, readability is increased with legibility. Also, reading is more enjoyable due to the correlation with the improved legibility. Users should not be obliged to zoom when discovering content from an m-commerce website interface or typing on the screen. Actionable targets should be clickable without zooming. This means that the text size and the colored contrast between the text and the background color have to be strong enough to facilitate the readability of the content.

Among the few basic factors to consider when trying to improve MUE, accessibility proves to be essential to ensure that the content is available and visible on mobiles. It can be improved thanks to the “WCAG AA” Accessibility Standards. Web Content Accessibility Guidelines (WCAG) 2.0 define how to make Web content more accessible to people with disabilities.

“Following these guidelines will make content accessible to a wider range of people with disabilities, including blindness and low vision, deafness and hearing loss, learning disabilities, cognitive limitations, limited movement, speech disabilities, photosensitivity and combinations of these. Following these guidelines will also often make your Web content more usable to users in general” says W3C (2016).

These guidelines provide the necessary basics of any website, whether it will feature on smartphones, tablets, laptops, or desktop devices.

In order to improve MUE, speed of download turns out to be important too. As for e-commerce on large screens (laptop/desktop), a significant criticism that consumers raise about using the Internet

is that it often takes a long time to download web pages, according to Dennis (2001) in Gorn *et al.* (2014). One of the mobile user's primary goals is to obtain information as quickly as possible while completing online tasks on the go. This particular problem is only becoming worse as webpages become more and more technical, with features enabling more interactivity or the integration of rich content (video, animation), increasing the page weight and its downloading time. A proper color contrast enables users to find the information more quickly, diminishing the frustration of a slow downloading time. The initial feelings experienced by a user is crucial because during the first 50 milliseconds users decide whether or not to continue browsing the website (Lindgaard *et al.*, 2006). The aim of designers is therefore to provide interactive systems that are not only useful and usable, but also capable of transmitting positive emotions through their aesthetic characteristics. The factors that slow down mobile pages encompass the number of requests (loaded video, images, scripts, etc.) followed by the quantity of bytes (page size).

The MUE of an m-commerce website also benefits from its structure. If the main information users/consumers need to locate is at the top of the webpage, users do not have to scroll down and run the risk of starting to feel irritated by not discovering the content they expect to find. This region is also called "*above the fold*" by web designers. It is characterized by a thin zone directly at the top of any website. A single-column layout providing the priority content at the top in an easy-to-read way can be a solution to retain the engagement of users who do not expect to scroll down systematically when they look for a product or service.

Diminishing the content to be read, whether with titles or paragraphs, also plays in favor of a greater MUE. Since less content to read also means

less tiredness, users may be sensitive to shorter texts provided on an m-commerce website, which preserve the principles of visual and cognitive ergonomics (Ling and Schaik, 2002). Leveraging creative copywriting and considering visual symbols such as icons to replace or reduce the copy represent interesting solutions, and this is why some actors are becoming key factors of success for successful interfaces. Some websites¹ provide toolkits for web designers in order to entice them to use vectors rather than images. Such actions help to diminish the size of a webpage. Indeed, these vectors give web designers scalable vector icons that can be instantly customized thanks to particular variables such as text size, color, drop shadow, and anything that can be done with the CSS.

Besides traditional landing page optimization fundamentals, web designers focusing on mobile tactics should concentrate on simple usability (reading/clicking), fast performance, minimal yet compelling action and easy-to-read content, thanks to a strong contrast between the foreground and background. Practitioners are advised to emphasize strong contrast between the foreground and background, especially for text messages. An important factor is appearance, particularly the proper choice of font and color contrast, which creates reliability and enhances e-service quality or perception if the website is user-friendly (Lowry *et al.*, 2014). Thus, we can hypothesize:

- H1:** The color contrast of the mobile website positively influences purchase intentions.
- H2:** The color contrast of the mobile website positively influences revisit intentions.
- H3:** The color contrast of the mobile website positively influences recommendation intentions.

Figure 1. Conceptual model

Following on from these hypotheses, we propose the following conceptual model:

METHODOLOGY

Conditions of the Survey, Stimuli and Data Collection

Respondents answered the questionnaire in the real-life, outdoor conditions of using a smartphone. For this reason, respondents were tested for color blindness using the Ishihara test² (Pelet, 2010). This guaranteed the validity of our sample's responses, by retaining only those people with perfect color vision. In order to control environmental variables, the ambient lighting³, humidity⁴ and temperature⁵ were also measured during each respondent's visit. These measurements enabled us to neutralize variables and were reported on each questionnaire of every respondent.

Two versions of a mobile website specializing in the sale of music CDs were especially designed for this experimental study: a site with a positive contrast (yellow text on a green background) and another with a negative contrast (green text on a yellow background). The experimental site contains 30 CDs available in 10 categories (3 CDs / category). For each CD, participants could see the CD cover, the album title, the artist's name and other details (music category, status (new or used), price, delivery time, etc.).

312 participants visited the site's two versions: 160 participants for the site with positive contrast

and 152 participants for the site with negative contrast. Each participant was required to view the details of at least two CDs of their choice and add them to their cart without making real purchases. After viewing at least two CDs, a link appeared asking them to respond to a questionnaire.

The questionnaire includes measures related to site design (5 items borrowed from Bressolles, 2006), intention to revisit (3 items of Mukherjee & Nath, 2007), purchase intent (4 items of Limayem & Rowe, 2006) and intention to recommend (3 items of Goyette *et al.*, 2010).

Validation of Measurement Scales

The measurement scales have a good internal consistency (Cronbach α and ρ of Jöreskog are above 0.7). The average variance extracted (AVE) by items is greater than 0.5. The variance extracted by each construct is greater than the squared correlations among constructs (Fornell & Larker, 1981), thus discriminant validity was supported. The indices for the measurement model also indicate a good fit (RMSEA = .08, RMR = .03, $\chi^2/df = 3.27$, $p < .01$).

Hypothesis Testing

The hypotheses were tested using the method of structural equations (AMOS). Their validity was verified for mobile websites with positive and negative contrast. The results are presented in Table 1.

Table 1. Test of the hypotheses

	Site With Negative Contrast (Green Text on a Yellow Background)				Site With Positive Contrast (Yellow Text on a Green Background)			
	Estim	S.E.	C.R.		Estim	S.E.	C.R.	
Revis<--- Desig	.10	.04	2.73**	H1 partially supported	.23	.03	7.00**	H1 supported
Buy<--- Desig	.02	.04	0.36		.20	.04	5.30**	
Recom<--- Desig	.16	.04	4.40**		.17	.03	5.21**	

Note: ** p <.01 ; * p <.05

Results show that the website's positive contrast has a significant impact on purchase, revisit and recommendation intentions. Unlike the site with positive contrast, the website's negative contrast does not influence purchase intent.

FUTURE RESEARCH DIRECTIONS

Our results show that the color contrast of a mobile commerce website, in particular a positive contrast, strongly influences the consumer's behavioral intentions in external conditions. It should also be noted that the consumer would be more inclined to buy from the mobile website with a positive contrast (in our case, a yellow text on a green background). On a mobile website, in the outdoor conditions of the experimentation, respondents have better behavioral intentions when the contrast ratio is a bright text over a dark background (positive contrast), which is the opposite of most actual mainstream websites, which use dark texts such as black over bright backgrounds such as white (negative contrast) (see figure 1):

In conditions where the sun shines and where it is often quite difficult to read the smartphone screen, users seem to prefer positive contrasts. Interestingly, this contrast exists in any smartphone as an "accessibility" option, in the "View" folder of the "Settings" section when pressing the "Negative Colors" button. However, it is not very easy to set up, especially when the lighting conditions are difficult, such as when the sun shines. An initial managerial implication of this research could therefore be to make this service available when the image sensor of the smartphone detects the sunshine and automatically switches it on when it reaches a certain level. This would enhance the legibility of the screen and protect users' eyes at the same time.

A second managerial implication that comes from this finding is that it could save the smartphone battery somewhat. It uses more energy to show a bright screen than a dark one. This is why a smartphone turns itself off relatively quickly when we do not touch its screen: in order to preserve the battery life, the more it shows a black screen, the less energy it uses. A website

Table 2. Comparison of Contrast polarity, External Environmental Condition and Interface used for the experimentation

Contrast Polarity	Site with negative contrast (Green text on a yellow background)	Site with positive contrast (Yellow text on a green background)
External Environmental Condition	Indoor conditions (laptop/desktop) Insert Image 2 (laptop_no_300dpi.tif) here	Outdoor conditions (mobile devices) Insert Image 3 (laptop_yes_300dpi.tif) here
Interface	Insert Image 4 (css0_Diana_300dpi.tif) here	Insert Image 5 (css7_Diana_300dpi.tif) here

that is predominantly made up of dark colors rather than bright colors may help to save the battery life and therefore preserve the environment: it becomes an “eco-friendly” strategy for the brands which work in this way and make users “Socially Conscious Consumers”, as depicted by Brooker (1976).

Our study contributes to a better understanding of consumer behavior surrounding mobile websites. Nevertheless, some limitations may be noted. Consideration of other variables such as feelings of privacy and perceptions of waiting time could provide more details about the purchasing behavior of people with sight problems. Maintaining constant levels of brightness and saturation, which are two components of color (along with hue), to study the overall effect of color on behavioral intentions without distinguishing the effect of text color from background color is one limitation of this research. Future studies are advised to consider other colors and to separately examine the effect of background color, and text color, as well as the interaction between the two. Moreover, there is still no agreement on whether human reactions to color are innate or learned and whether they can be conditioned by each individual’s social experience (Crozier, 1999). Cultural aspects must also be taken into consideration insofar as we perceive color differently according to our origins.

CONCLUSION

Whereas smartphones continue to offer more and more graphic possibilities thanks to their ever-growing power, enabling them to show more than 16 billion colors, our eyes enable us to distinguish only 8 billion (Chrisment *et al.*, 1994). Among these, it is easy to create contrast ratios that enable users suffering from color blindness, as well as other sight problems, to exploit free and easy-to-use tools (for a list of these, please visit <http://www.scoop.it/t/color>). As already described

by Pelet & Papadopoulou (2012), by taking into account the W3C and Web Accessibility Initiative (WAI) guidelines⁶, the use of color becomes more professional and the choices web designers make are more informed in terms of usability, as well as in terms of human-computer interaction in general.

ACKNOWLEDGMENT

The authors would like to thank reviewers from the « First International Conference on Advanced Research Methods and Analytics », CARMA 2016, Universitat Politècnica de València, València, Spain, 2016. DOI: <http://dx.doi.org/10.4995/CARMA2016.2016.3110> for their thorough review which helped to improve the research. The present chapter is an enhanced version of the paper published prior to the aforementioned conference, available at: <http://ocs.editorial.upv.es/index.php/CARMA/CARMA2016/paper/view/3110>

KEY TERMS AND DEFINITIONS

Contrast: is the difference in luminance and/or color that makes an object (or its representation in an image or display) distinguishable. In visual perception of the real world, contrast is determined by the difference in the color and brightness of the object and other objects within the same field of view. Because the human visual system is more sensitive to contrast than absolute luminance, we can perceive the world similarly regardless of the huge changes in illumination over the day or from place to place. The maximum contrast of an image is the contrast ratio or dynamic range. Finally, contrast is the perceived difference in colors that are in close proximity to each other. Using contrast effectively not only differentiates a design from others, it is the essential ingredient that makes content accessible to every viewer, on a laptop or a handled device such as a smartphone or tablet.

ENDNOTES

¹ Websites such as “<http://fontawesome.io/>” enable the use of metaphoric icons.

- ² The Ishihara test is the most common color blindness test used today (Deeb & Motulsky, 2011). It consists of a number of plates, either 24 or 38, (these are known as the Ishihara plates), each containing a circle of dots which appear in random colors and sizes. Within the circle are dots forming a number which should be clearly visible to viewers with normal color vision and hard to see or invisible to viewers with defective color vision. To pass the test, participants should recognize the number in every plate.
- ³ An interval between 300 lux and 500 lux was fixed.
- ⁴ A maximum of 65% humidity was retained.
- ⁵ Data were collected when the temperature ranged from 19 to 29°C.
- ⁶ The Web Access Initiative (WAI) works with the W3C (World Wide Web Consortium) working groups to address and improve accessibility within specifications and W3C technologies.

Ethical Ambiguities in the Privacy Policies of Mobile Health and Fitness Applications

M**Devjani Sen***University of Ottawa, Canada***Rukhsana Ahmed***University of Ottawa, Canada*

INTRODUCTION

Mobile leisure, health, and wellness applications (apps) are ubiquitous. A recent study reveals that there are approximately 97,000 varieties of inexpensive and easy to use mobile health apps available in the market; at such a pace numbers are becoming outdated almost as soon as they are published (Privacy Clearinghouse, 2013). It is predicted that by 2017 half of the world's more than 3.4 billion smart phone users will have downloaded health and fitness apps (Comstock, 2013), which raises the question: what happens to the sensitive data consumers enter into these apps?

Indeed, a hot topic in both Canada and the U.S., concerns exactly what third parties, such as insurance companies, can legally do with personal data. American law dictates that health insurance companies cannot discriminate based on a history of illness. However, while data held by a health plan, health care provider, or lab may be protected by the federal Health Insurance Portability and Accountability Act (HIPAA), legal scholars warn that if a patient is going to upload health or wellness data to a mobile application (app), it may not be covered by those laws (Rogers, 2014; Whitman & Mattord, 2012). Such legal ambiguities have implications for Canadian users of health and wellness apps, because many of these devices are based in the U.S., with the data being stored on U.S. servers and thus they may not conform to privacy requirements (Akkad, 2013).

There are some other important concerns with privacy and security issues related to mobile health and fitness applications. For example, personal apps collect all sorts of personal information like name, email address, age, height, weight, and in some cases detailed health information. When using such apps, many users may trustfully log everything from diet to sleep patterns in the apps. By sharing such personal information end-users may make themselves targets to misuse of this information by unknown third parties. Moreover, according to Gralla et al. (2011), apps can gather the phone number and the unique ID number of each type of phone: the Unique Device Identifier (UDID) on an iPhone, the International Mobile Equipment Identity (IMEI) number on a BlackBerry, and (depending on the make) the IMEI or the Mobile Equipment Identifier (MEID) on an Android phone. In this way, personal information that apps gather about an end-user can be matched to these IDs, which means that ad networks can easily combine various pieces of information collected by multiple apps to build a sophisticated profile about a given end-user and thereby posing a major privacy risk to personal data. Therefore, uninformed decision making by end-users raises important concerns regarding the ethics around sharing personal data gathered from health and fitness apps to third parties. These concerns can be much graver when Martínez-Pérez and colleagues (2014), in a review of privacy and security in mobile health apps, found evidence of insecure handling of clinical and medical data.

DOI: 10.4018/978-1-5225-2255-3.ch528

To summarize, the issues raised above may be broken down to the following concerns:

1. Ownership and veracity of sensitive data shared on personal apps;
2. What end users really understand about the use of their data (what data is collected and the specifics of how it may be used);
3. The ethics of sharing end-users' personal information and sharing it with third-parties.

Despite the important role of informed consent in the creation of health and fitness mobile applications, the intersection of ethics and sharing of personal information is understudied and is an often-ignored topic during the creation of mobile apps. After reviewing the online privacy policies of a select set of mobile health and fitness apps, this chapter will conclude with a set of recommendations when designing privacy policies for the sharing of personal information collected from health and fitness apps.

BACKGROUND

Online privacy policies, which regulate the relationship between the user and the website with the purpose of limiting companies' legal liability during site use, are also used by users to inform their understanding of the ways personal data are treated by companies. Despite their importance to users, however, studies suggest that these policies are often ignored (Angulo, Fischer-Hübner, Westlund, & Pulls, 2012; Jensen & Potts, 2004; Kesan, Hayes, & Bashir, 2012; Tsai, Egelman, Cranor, & Acquisti, 2011). As pointed out by Steinfeld (2016), since agreeing to the terms of the policy is usually a prerequisite for subscribing to a website or a web service, users typically sign their consent almost automatically, so that these terms are rarely considered as reasons for joining or avoiding a given website.

Studies suggest that many apps do not have a privacy policy, or that apps do not grant users

access to and control over personal information before users download and/or after use apps (Privacy Rights Clearinghouse, 2013). Nevertheless, having a privacy policy or providing a link to it is not enough to safeguard end-users' right to data privacy. Studies have also identified a number of cognitive factors which limit the comprehension of existing privacy policies, including complexity, legal language, and length (Angulo et al., 2012; Milne & Culnan, 2004; Nissenbaum, 2011; Tsai et al., 2011), use of vague terms and concepts (Anton et al., 2003), as well as design issues such as format and font size (Milne & Culnan, 2004).

IDENTIFYING PRIVACY RISKS IN HEALTH AND FITNESS APPLICATION PRIVACY POLICIES

Clearly, if privacy policies are not being read, there is a need for more readable policies that will be better understood and will more effectively inform users decisions on whether it is prudent for them to join a given website service agreement. Indeed, given the varied educational levels and socio-economic backgrounds of online consumers that encompasses a wide range of the global population, it is critical that companies communicate effectively with customers through their online privacy policies (Wheatman & Ghiselli, 2014). With these considerations in mind, the purpose of the present chapter was to investigate the presence of important information and its presentation in plain language format in privacy policies of health and fitness applications. To this end, a close examination of the privacy policies of selected commonly used health and fitness applications was performed. Considering the limited scope of this chapter, the number of apps to examine was limited to four in order to properly execute a combined approach of using a checklist and discussing relevant excerpts from the selected privacy policies.

Health and fitness applications are application programs that offer health-related services on

portable devices such as smartphones and tablet PCs. The apps examined in this chapter included: 1) Fitbit, which records data such as the number of steps walked, heart rate, quality of sleep, steps climbed, and other personal metrics; 2) JEFIT, a free app that records and logs fitness exercises, tracks workouts and progress, enables access to a large exercise database; 3) Nike Training Club, which gives the user a personal trainer, with more than 60 custom-built workouts from a Nike Professional Trainer as well as enables user to sync their results to social media sites such as Facebook to show friends how training is going; and 4) MyFitnessPal, a free calorie counter smartphone application and website, which helps to track calorie intake for exercise and diet and employs gamification elements to engage and motivate users to achieve their goals. In order to ensure that the health and fitness apps examined comprised popular apps with a wide user base, the selection criteria for each app was set at a minimum of one million downloads. Care was also taken to ensure that: a) each app had an androgynous user base, having an equal appeal for male and female users

and b) two of the four apps in the sample included free apps considering such apps are expected to hold greater biases for selling material to third party sites. It is also important to note that the apps selected offer a diversity of core functions, including recording, logging and tracking personal metrics, diet, exercise and workout routines and progress, even working with certified personal trainers.

In order to assess the privacy policies of the selected four health and fitness apps, a checklist was used that comprised five privacy risk categories. These privacy risks were based on two questions: a) is important information missing to make informed decisions about the use of personal data? and b) is information being shared that might compromise the end-user's right to privacy of that information? The two authors of this chapter examined the online privacy policies of each selected app in search of important privacy risks. Based on their search, each author completed a separate checklist and compared their findings to reach an agreement of the presence or absence of each privacy risk category. Table 1 outlines the

Table 1. Checklist of privacy risks for Fitbit, JEFIT, Nike and MyFitnessPal mobile applications

Description of Privacy Risk	Fitbit	JEFIT	MyFitnessPal	Nike Training Club
Explicitly stated that under no circumstances will Personal Identifiers (PI) be shared	×	×	×	×
Use of cookies explicitly stated as well as what information is tracked and how it is used	√	√	√	√
Explicitly stated what sharing is done with third party sites and the security regarding links to other Sites	√	√	√	√
Location and use of personal data after account is deactivated	√	×	×	×
Ownership of data is stated clearly when device is used by international users	√	×	√	√

results of the final checklist assessing the occurrence of each privacy risk examined.

The following section will discuss in further detail the subsections from the checklist from the assessment of the privacy policies of the four health and fitness applications.

Type of Data Collected Explicitly Explained and it is Stated What is Done With Personally Identified (PI) Data

Regarding personal identifiers, JEFIT (2015) states:

The information we collect in order to create your JEFIT.com account includes data such as your name and email address. The email address may be used to contact you with matters regarding JEFIT, such as a newsletter, notifications of new messages from other JEFIT members, or an announcement about a new product or service. We also collect some personal fitness information so that we can provide you with a personalized plan for successful weight loss. JEFIT also collects other profile data including but not limited to: personal interests, geographical location, gender, and age in order to assist our members find and communicate with each other. JEFIT collects personal information about you when you sign up for a JEFIT account. This information includes your age, metric preferences, and other personal fitness details. JEFIT also stores the data you enter about workouts, exercise, and anything you choose to track and keep records of.

When referring to non-personally-identifiable information, the policy states:

JEFIT also logs non-personally-identifiable information including IP address, profile information, aggregate user data, and browser type, from users and visitors to the site. This data is used to manage the website, track usage and improve the website services. This non-personally-identifiable

information may be shared with third-parties to provide more relevant services and advertisements to members. User IP addresses are recorded for security and monitoring purposes.

From the above excerpts, it is not completely clear whether non-personally-identifiable information may be shared with third-parties. It is simply stated that personal information is stored and collected, without further explanation about the purpose of this storing and collecting. What does it really mean to use this data to provide the end-user with a personalized plan for successful weight loss? Does it mean sharing this information with third parties who can advise on how to best do this?

Further, in the section entitled Privacy Policy Change, JEFIT (2015) states:

When you use the JEFIT.com sites to provide personally identifiable information, you consent to the collection and use of that information in accordance with this privacy policy.

What does this statement convey? Again, the intended or planned use of the collected and stored personally identifiable information is not clearly communicated.

Finally, of the privacy policies of the four health and fitness applications explored, the most alarming ambiguity seems to be stated in the privacy policy of MyFitnessPal (2013):

Except as otherwise provided in this Privacy Policy, and when You otherwise give permission or under the following circumstances, MyFitnessPal will not share Your Personal Information with third parties.

However, what is stated in subsection User Content, under Terms and Use, appears to conflict with (interestingly located in a poor visibility area of 19th bullet) MyFitnessPal's (2013) explicit statement regarding the PI data that the company can do whatever it chooses with the end-users personal data:

“User Content” is any content, materials or information (e.g., any text, information, photos, images, video, and other content and material, including nutritional information contributed to the Food Database) that You upload or post to, or transmit, display, perform or distribute by means of, the Services, whether in connection with Your use of Website, Application, or through the use of any Third Party Websites or Third Party Services or otherwise. You hereby grant MyFitnessPal and its officers, directors, employees, agents, affiliates, representatives, service providers, partners, sublicensees, successors, and assigns (collectively, the “MyFitnessPal Parties”) a perpetual, fully paid-up, worldwide, sublicensable, irrevocable, assignable license to copy, distribute, publish, transmit, publicly display or perform, edit, modify, translate, reformat and otherwise use User Content in connection with the operation of the Services or any other similar services or related business, in any medium now existing or later devised, including without limitation in advertising and publicity. You further agree that this license includes the right for the MyFitnessPal Parties to publish, display or otherwise use and make available your User Content and possibly your name and/or any user name of yours in connection with their exercise of the license granted under this section. You agree to waive, and hereby waive, any claims arising from or relating to the exercise by the MyFitnessPal Parties of the rights granted under this section, including without limitation any claims relating to your rights of personal privacy and publicity.

Regarding personal identifiers, Fitbit (2016) states the following:

We will never sell your data, and will only share personally identifiable data when you direct us to (or under the circumstances outlined in our Privacy Policy).

Although this information appears to be clear, it might not be understood the same way by dif-

ferent users. For example, many people might understand the above to mean that if they do not give explicit consent their data will not be shared. However, it could also be that directing data to be shared might occur in other more covert ways that most end-users are not aware of.

While NIKE (2014) does state in what ways PIs may be shared with other parties, they also explicitly state:

However, like other companies, NIKE cannot guarantee 100% the security or confidentiality of the information you provide to us.

Use of Cookies, What Information is Tracked and How it is Used

Most privacy policies of the health and fitness applications examined defined what is meant by cookies and what they do (how they track information) and give details about how to disable cookies. However, many useful features of fitness apps warrant the use of entering in information that might be tracked by cookies. As Fitbit (2016) states:

When You Add Information to Your Account

You can customize your Fitbit experience by adding other types of information to your account, such as entering a food log or setting an alarm, personalizing your profile with photos, participating in discussion boards, or sending messages to your Fitbit friends. Whenever you add this type of data, we collect it and store it in your Fitbit account.

This statement raises the question of whether it is realistic for all cookies to be disabled. For example is it reasonable to expect a user to sign into a fitness app where they never enter information into food logs, set an alarm, participate in discussion boards, add photos to their profile, or interact with their friends who have this same app?

Sharing with Third Party Sites

On the whole, this section was well done by the four mobile application privacy policies examined. All apps stated that if end-users choose to share their information with Third Party Sites, they need to carefully read the privacy policies of these third party sites. This way, sharing of personal information with third party sites may likely happen with end-users' knowledge and based on their informed decision.

Location and Use of Personal Data After Account is De-Activated

With the exception of Fitbit, it was not possible to clearly locate information on what happens to personal information once the user de-activates his or her account. Fitbit (2016) states:

You can deactivate your Fitbit account by contacting Customer Support. When you do, data that can identify you will be removed from the Fitbit Service, including but not limited to your email, name, photo(s), friends list and links to sites such as Facebook and Twitter. Backup copies of this data will be removed from our server based upon an automated schedule, which means it may persist in our archive for a short period. Fitbit may continue to use your de-identified data after you deactivate your account.

This statement raises two questions: 1) what happens to PIs during the short period of time referred to? and 2) what is the length of this period of time? Clearly more attention needs to be given to these important issues in terms of clarity and completeness of the information provided.

Ownership of Data is Stated Clearly When Device is Used by International Users

Only Fitbit (2016) clearly stated that the U.S. Privacy Policies do not apply to the sharing of

personal data when using Fitbit devices outside the United States. Interestingly, although NIKE (2014) and MyFitnessPal (2013) also stated this information, it was missed entirely by one of the authors due to poor visibility. This may be an important concern for international use of such devices by travelers from the U.S. in addition to end-users who reside in other countries.

RECOMMENDATIONS

Based on the review of the online privacy policies of four mobile health and fitness applications, and reflecting on the analysis of ambiguities and privacy risks in the privacy policies of those apps, the following recommendations are offered. Although these recommendations should be taken into consideration when designing privacy policies for the sharing of personal information collected from health and fitness apps, they can also be extended to the creation of privacy policies of other mobile apps and web services such as in the areas of human resources, planning and project management, customer engagement, property management, education and training:

1. It is suggested that personally identifiable information be stated clearly; PI and non-PI information should be clearly distinguished. It is also important to clearly state what will never be done with PI data. Moreover, this information should be made highly visible (within the first page) of any Privacy Policy/Terms and Conditions;
2. It was found that cookies were clearly defined in the privacy policies of the apps examined. However, given that information is tracked and used by cookies, the kinds of activities that enable activation of cookies might need to be stated more clearly;
3. Generally, when the end-user enters a Third Party Site, its privacy policies apply. While it is recommended that this guideline be stated clearly, the need to read and exam-

ine these third party site privacy policies should be highlighted as well. Furthermore, if Contests and Giveaways comprise Third Party sites, this information also needs to be highlighted; at some part of a Contest or Giveaway advertisement, it clearly needs to be stated that the privacy policy of this site is now in effect (vs. the privacy policy of the original site);

4. It is advised that information regarding the location and use of personal data after an account is disabled be stated clearly in the privacy policies. Not doing so may suggest that all data is automatically deleted upon deactivation of an account. Hence, it is recommended that this information be clearly presented under a subheading such as What Happens When Your Account is De-Activated or something similar to this;
5. It is proposed that the rightful owner of data be more clearly stated when devices are used by international users and this information be stated in a clearly visible manner.

FUTURE RESEARCH DIRECTIONS

This encyclopedia provides a comprehensive summary of research-based chapters on copious aspects confronting the field of information science and technology. The rapid innovations and advances in Information and Communication Technologies (ICTs) and the growing rates at which these technologies are transforming lives around the world and shaping the future, demand incubation of inter/cross/transdisciplinary research agendas. On the one hand, technological innovations can significantly improve health care by enabling easier communication of electronic record of patient health information between different health care professionals (Mardis, 2013), reaching at-risk populations (Briones & Sundstrom, 2013), and so on. On the other hand, integrating ICTs into health care is complicated and it is a daunting process to create an ICT-driven

health care system that is accessible, reliable, safe, and thus effective (Avtgis & Polack, 2013). Future research should proceed with caution when considering the design of health and fitness applications on mobile devices to help safeguard privacy when sharing personal information on health and fitness apps.

As explored in this chapter, mobile health and fitness applications raise many pertinent yet unanswered questions for health care ethics. Many end-users may automatically consider health and fitness apps to be beneficial; but, there are complications that may arise from neglecting privacy and security concerns when sharing personal information on these apps. Overall, ICTs help facilitate access to health information and thus can help to increase awareness which translates to patient participation in their own health care. There is an app for just about any health, fitness, and weight-loss resolution. Amidst this myriad health and fitness apps that are permeating lives all around the globe, an important question of data privacy looms large: what happens when advertisers and other third parties share this information without the user's knowledge? Questions like this and others that remain largely unexplored and that have only recently been asked by scholars should guide future investigations. Future studies should continue to investigate the complexities at the intersection of ethics and information sharing on health and fitness apps in order to tap into the potential of mobile apps to improve health behavior and health care delivery.

Health and fitness mobile application development should integrate the end-user experience perspective. Future research should privilege the end-user voice in determining ethics, privacy, and security of personal data shared on these apps, and in co-designing guidelines for data protection. Surveys, focus groups, and interviews can help gather important information regarding end-user awareness and comprehension of data privacy. Such data could yield valuable information to aid in designing simple and user-friendly privacy policies. Researchers across disciplines should

continue to share good practices with regard to personal data use, sharing, and retention practices of health and fitness applications.

As the field of information science and technology continues to evolve, so do the available ICTs become integrated and may eventually be an integral part of the health care system. The end-users of mobile applications will have opportunities to influence developments in health information technologies that can lead to personalized tools to promote health and prevent disease. Yet, the intersections of ethics, privacy, security, and information sharing is understudied and is an often-ignored topic during the creation of mobile apps. In order to complement the research reported in this chapter, further exploration in the following areas is advocated for:

- A comprehensive review of privacy policies of the plethora of health and fitness applications that are available;
- Full investigation, from the perspectives of both app developers and end-users, of ethical ambiguities in privacy policies across health and fitness applications;
- An advancement of current understanding of how people with limited literacies – functional, health, digital, technology, and so on – use and apply health and fitness apps.

CONCLUSION

This chapter explored ambiguities in the privacy policies of selected health and fitness mobile applications. In doing so, it raises ethical and security concerns about sharing health and medical information online. Through its review of topics such as the ethics of information sharing on apps and online privacy policies, this chapter helped to advance knowledge on the dangers of sharing personal information on mobile apps, which can

jeopardize the rights to privacy of end-users of mobile apps.

Today's health care system greatly depends on information and communication technologies. These advancements facilitate communication between patients, doctors, and other health care professionals. Technology, with its many uses, continues to flourish as society continues to develop and expand. There are numerous benefits as well as negatives to using these technologies in the health care context.

Finally, this chapter calls for multidisciplinary and multisectoral research partnerships to best meet the challenges of today's information technologies. Health and fitness mobile applications will not address ethical and privacy concerns in and of itself. Researchers, practitioners, policy-makers, app developers, programmers, promoters, and users need to come together to debate and address these concerns.

KEY TERMS AND DEFINITIONS

Ethics: The critical examination of the advantages and disadvantages when deciding upon the correct conduct involving a moral issue.

Information Security: The process of protecting the availability, integrity and privacy of information.

Mobile Applications: A term used to describe Internet applications that run on portable devices such as smartphones and other mobile devices to make it easier for users to access the Internet.

Mobile Health and Fitness Applications: Application programs that offer health-related

services on portable devices such as smartphones and tablet computers.

Online Privacy Policy: A document, typically required by law, which regulates the relationship between the user and the website with the purpose of limiting companies' legal liability during site use.

Personal Identifiers Information (PIIs):

Comprises information, that when considered alone, or in combination with data from other sources, may contribute to distinguish (identify) an individual.

Privacy: An individual's right to control how and to what extent information about him or her may be shared and acted upon by others.

M

Exploring the Growth of Wireless Communications Systems and Challenges Facing 4G Networks

Amber A. Smith-Ditizio
Texas Woman's University, USA

Alan D. Smith
Robert Morris University, USA

INTRODUCTION

Wireless and Mobile Communications

In a traditional sense, wireless systems were considered as an auxiliary approach used in regions where it was difficult to build a connection by using typical wires and cables (Alderete & Gutiérrez, 2014). Firms operating in a competitive and global marketplace are relying more and more on the data that flows throughout their organization. As a means of enhancing supply chain management (SCM), firms are working to improve the integration level with suppliers and clients, materials and inventory regarding the production costs, influence of raw material prices, and the active request for changes by the client (Dharni, 2014; Gupta & Naqvi, 2014; Qrunfleh, Tarafdar, & Ragu-Nathan, 2012; Soon, Mahmood, Yin, Wan, Yuen, & Heng, 2015). Many organizations are seemingly more concerned with the identification of logistic issues as new opportunities arise. Even though changes in commercial activity are an important part of B2B (business-to-business) operations; for the most part, managers today do not comprehend insightful ways to deal with them. Many of the smaller firms that are integrated into a supply chain, lack the technological capacity to implement electronic operations of data processing, transmission of data, and reception of data (Qrunfleh, et al., 2012).

Originally, 1G-networks were introduced in the 1980s and were generally based on analog techniques. It built the basic structure of mobile communications and solved many fundamental problems. Some of these problems included cellular architecture adopting, multiplexing frequency band, roaming across domain, and non-interrupted communication. The only service of 1G was Speech Chat. Then, once implemented, 2G gained popular acceptance during the 1990s. It was based on digital signal processing techniques and regarded as a bridge from analog to digital technology. It introduced a new option of communication called text messaging, multimedia messaging or picture messaging, General Packet Radio Service, Wireless Application Protocol, Enhanced Data Rates for GSM Evolution, and Internet services. 2G's main contributions were the utilization of SIM (Subscriber Identity Module) cards and support capabilities for a large number of users (e.g., 2.5G was regarded as 3G services for 2G networks). This network extended the 2G network with data service and packet switching methods. 2.5G brought the Internet into mobile personal communications under the same networks with 2G, which was an important concept leading to different kinds and combinations of communications.

The 3G network, known as "the third generation mobile broadband data services", came with several incremental improvements in radio technology and command-and-control software.

DOI: 10.4018/978-1-5225-2255-3.ch529

Radio advancements of the 3G network are referred to as antenna techniques or coding/modulation schemes. According to Akintoye (2013, p. 43), “Several new radio techniques are employed to achieve high rates and low latencies.” These new radio techniques included Space Division Multiplexing (SDM) via Multiple Input/Multiple Output (MIMO), Space Time Coding (STC) using higher order of modulation, and encoding schemes, beam forming, beam directional control, and inter-cell interference techniques. These growths in wireless data services have placed higher demands on mobile wireless networks, and in response, wireless carriers are upgrading their networks to offer faster data rates (Latha & Suganthi, 2015; Sundarambal, Dhivya, & Anbalagan, 2010).

BACKGROUND

Mobile Systems and 4G

The use of mobile wireless data services continues to increase worldwide. Mobile systems focus on effortlessly integrating the current wireless technologies including global system for mobile communication, wireless local area networks, and Bluetooth. Ultimately, 4G systems support comprehensive and personalized services. These factors are essential in providing stable system performance and quality service. According to Akintoye (2013), the 4G platform as a mobile multimedia, universally available, global mobility support, integrated wireless, and e-customized service network system. It was designed to use a number of types of broadband wireless access communication systems and to work side-by-side cellular telephone systems.

The official 4G-based requirements are set and published by International Telecommunication Union (ITU). It specified a number 4G-based requirements that can be grouped into 5 types: data rates (i.e., cell spectral efficiency, peak spectral efficiency, cell-edge user spectral efficiency, mobility data rates), latency, handover interruption

time, RF bandwidth, and number of active voice-over-Internet (VoI) protocol users (Yang, 2012). A 4G cellular system must have target peak data rates of up to approximately 100 Mbit/s for high mobility, such as mobile access. For low mobility, one needs data rates up to approximately 1 Gbit/s, such as local wireless access. The higher 4G data rates are available in those areas in which 4G cellular service is provided. They should provide scalable bandwidths of up to at least 40 MHz. A 4G system is expected to provide a comprehensive and secure all-IP based solution where facilities such as IP telephony, ultra-broadband Internet access, gaming services, and high-definition television streamed multimedia may be provided to users. It is very helpful for any organizations' compliance with e-Discovery requests.

In 4G networks, users are joining the network through add mobile routers to the network infrastructure. Wherever the concentration of customers is in more in one area, additional routes are created, enabling further access to network capacity. Hence, network capacity and coverage has dynamically shifted to make available more appts and high-speed connections available to suit changing user patterns. This enhanced flexibility permits the network to vigorously and routinely balance capacity and increase network utilization. As with web-based technologies, 4G is playing a significant role in promoting social networking and social media uses.

Business Audience for 4G

4G wireless communications are used in many businesses throughout the global economy and its vast communication networks to enhance and improve productivity. Each of the 5 major U.S. network operators (e.g., Verizon Wireless: 142.8 million (Q2 2016), AT&T Mobility: 133.3 million (Q3 2016), T-Mobile US: 69.4 million (Q3 2016), Sprint Corporation: 60.2 million (Q3 2016), U.S. Cellular: 4.9 million (Q2 2016)] (“List of United States wireless...” 2016) offers a slightly different version of 4G wireless communication services

that provide significantly faster data speeds than its 3G networks. Verizon is vastly expanding its 4G network based on the Long Term Evolution (LTE) standard.

LTE is a standard for wireless communications for mobile phones based on packet switching. This is an entirely different approach from the circuit-switching approach employed in 3G telecommunications networks. Carriers must basically recreate their voice call networks to convert to the LTE standard. The Sprint version of 4G network is based on the WiMAX (Worldwide Interoperability for Microwave Access) standard. This standard is of a faster speed than traditionally offered 3G networks, but not as fast as networks based on LTE. WiMAX operates like Wi-Fi in many aspects, only over greater distances and at faster transmission speeds. Fewer WiMAX base stations are required to cover the same geographical area than when Wi-Fi technology is used. The AT&T and T-Mobile 4G networks are based on the HSPA+ (Evolved High Speed Packet Access) standard, with AT&T speedily converting from HSPA+ to the LTE standard. HSPA+ is a broadband telecommunications standard. These network providers rely heavily on 4G to operate their routine business operations in order to be profitable in this highly competitive environment.

Advantages of 4G

When 3G was introduced to the market, the technology did not have enough advantages compared to the 2G. Obviously, it was an improvement compared to 2G, but 3G did not bring consumers to transition fast from 2G to 3G wireless network technologies, perhaps due to speed and options-related improvements were not significant enough for consumers to invest money and change their devices. However, that was not the case when 4G wireless mobile communication networks were developed. 4G had way more advantages over previous networks such as 2G or 3G, so everyone wanted to adapt to the new technology and enjoy all the advantages it could offer.

An important advantage that 4G offered technology was user friendly. Another goal was to provide countless services to the users at relative high speeds. For example, making devices to recognize the user's voice and execute appropriate commands that allow users to achieve their goals more efficiently and in less time. Perhaps, one of the most significant advantages of 4G is that it provides opportunity to access the Internet basically from anywhere by using wireless devices. This advantage helps to provide enhanced user personalization opportunities. For example, when a user is accessing repository of data or other services, the user has the ability to set up service features that would be used the most.

Terminal and Network heterogeneity is another advantage provided by 4G wireless networks, and in other words, it means service personalization. This gives the opportunity to pick an access to the network between WiMAX, Wi-Fi, or Universal Mobile Telecommunications System. This 4G wireless network provides high performance. One of the most impressive facts about 4G is its download speeds when compared to 3G technologies. In general, 4G networks are about 260 times faster than previous generations (i.e., 3G wireless networks). Interoperability is one of other many advantages this technology offers, for example, it gives options for users to use all kind of services from multiple suppliers by using the same mobile device and nowadays this is an important thing to have because there are so many options and everyone would like to have access to those options.

One of the most impressive advantages is its Intelligent Networking. 4G wireless technologies are trying to use Wireless LAN and WAN designs to promote ease of use and widespread acceptance. Many businesses and educational institutions are moving more and more towards e-commerce and web-based standards (Chand, Raj, & Shankar, 2015; Elysee, 2015; Han, Ada, Sharman, Gray, & Simha, 2015; Latha & Suganthi, 2015; Shukai, Chaudhari, & Dash, 2010; Sundarambal, et al., 2010). So, in order to conduct business more effectively, Internet access is needed, so many

businesses, in order to attract more customers, decided to create Wi-Fi spots in their facilities and share it with their customers (Daim, Basoglu, & Tanoglu, 2010; Daramola, Oladipupo, & Musa, 2010; Dominic, Goh, Wong, & Chen, 2010). As evident in the wide-spread practice of Wi-Fi and 4Gspots in malls, restaurants, libraries, service centers, etc.; hence, not having the opportunity to get connected to Wi-Fi, or forced to use GPRS services can be a great disadvantage to businesses and other institutions in attracting customers. However, then the place with the Wi-Fi connection is reached by the user; mobile device would automatically switch to use this connection (LAN design) without any actions performed by the customer. This is called Intelligent Networking and is thought to be a significant advantage.

Network convergence is a major advantage that 4G can provide to its users. One of the goals of creating 4G wireless networks was to integrate it to the global IP based network, and the plan was to blend devices and services together. Since this innovation was getting popular, scalability was really important, and it was solved by using IPv6 addressing scheme, which can provide access to a large number of users who have wireless devices. This eliminates the need for Network Address Translation (NAT). Users of this technology are still increasing and scalability provides a big advantage. Those kinds of technologies, such as 2G or 3G, have huge effect on battery life; however, 4G is trying to minimize that problem and convert it into advantage. A possible solution that was proposed was to reduce battery usage by this technology to create shorter communication links. Finally, another advantage concerning 4G wireless technology is that does not generate significant expenses or burdens for users. They do not need to buy any additional accessories in order to make it more efficient. In-other-words, it is not a completely new system, but it is built on the existing networks, so it supports the use of 2G or 3G. This is one of the reasons why it is cheaper and does not require any additional spending for the users.

4G provides way more advantages compared to what 3G had to offer when it was released. The above listed advantages are the reasons why users are using more and more of 4G wireless services nowadays. 4G made it really convenient for the user to adopt this new technology from the beginning, made it more scalable, efficient, and most importantly, there is little additional costs associated with the adoption this new technology (Aeron, Kumar, & Janakiraman, 2010; Barra, Savage, & Tsay, 2010; Smith, 2013, 2014; Smith & Synowka, 2014; Smith & Rupp, 2013; Smith, Synowka, & Smith, 2014)..

Challenges Facing 4G Networks

There are a number of challenges 4G wireless network faces, such as security and privacy issues, quality of service, and complex architecture (Sinha & Thirumalai, 2011; Smock, Ellison, Lampe & Wohn, (2011). These are the challenges that should be overcome in order to provide more efficient and safer wireless network for the users. Security and privacy issues are really important in today's world because hackers are accessing users' private information, such as home address, credit card codes, and/or social security number. So, there are urgently needs to provide users with safe ways to send and receive information through the network. 4G networks may higher likelihood of security attacks due to its widespread adoption, so preventative measures and additional security levels created such as identification of the user and identification of IP addresses from where a user connects to the network or passwords should be safeguarded. These methods might help to protect the data, which is about to be transferred through the network.

4G wireless networks are trying to provide the highest quality of service, such as improved connectivity, faster speed, and enhanced accessibility. Unfortunately, one of the challenges it faces is connecting non-IP-based and IP based devices. These two devices are used for different purposes. Non-IP based devices are used for Voice-over Internet Protocol (VoIP), while IP

based devices are usually used for transferring data. 4G networks are trying to serve both devices, but creating mechanisms in order to do that effectively creates protocols and connectivity problems that must be addressed.

Another challenge facing 4G wireless network integration is its complex architecture. In order to reduce the operating cost or power consumption, networks should be able to be operational and functional in different working environments. Multi-mode devices were one of the suggested solutions in order to fix this problem because it allows for the device to adapt to various networks by using a software radio. Another challenge 4G faces is system discovery and selection because wireless devices are receiving all kinds of signals from various systems and after processing those signals its need to determine the most appropriate service provider in order to provide proper connections. Some potential solutions to connectivity problems might not be available in a timely manner due to their regulations, rules or location. However, the solution proposed to solve this challenge was system-initiated discoveries, and this program is able to find automatically the best software module. Lastly, supervising customers' accounts and sending bills to their 4G network made it more complicated and the main reason is heterogeneity of 4G networks.

Successful Application of 4G

Technology is continuously evolving and even over the past decade there have been drastic changes to accompany how individuals in society operate and communicate to each other. In years past, cellphones were made for solely making phone calls, while smart phones and tablets and their numerous applications were simply fantasy or science fiction. People not only rely on cellphones, tablets, and computers for making phone calls and sending e-mails, but they are used to do activities such as banking, send text messages, video chat with someone in a different location, shop online, and so much more.

4G networks are widely advertised and advanced the need for widespread wireless communication connectivity. One of its main features of 4G networks over previous networks is that it provides high-speed connections and it gives users the opportunity to utilize these networks outside of their personal space. Other advantages this network offers includes: intelligent networking, network convergence, scalability, lowers power consumption, and lower operational costs. Not only are individuals utilizing these services for personal day-to-day needs but businesses have become involved and are benefiting from the 4G network as well. One business in particular is the White House Utility District (WHUD), which is located in White House, TN.

The WHUD is one of the largest water and sewer utilities in Tennessee, serving a large population of 90,000 with over 30,000 connections within a 600-square-mile ("White House Utility District," 2016). The use of a 4G network has drastically improved communication, effectiveness, and the overall quality of how the WHUD operates and manages the communication needs of both its employees and their customers. An important benefit of 4G is that it allows maintenance crews to be alerted quickly, ultimately resulting in faster response times. This is due in part that essentially all of the employees of WHUD are provided with 4G phones and tablets. Other 4G network-based services offered that benefit customers include the ability to pay bills online, check account balances, establish or discontinue service with the company, update account information. For example, there are educational programs that are offered to inform customers about its efforts to ensure safe drinking water by logging on to their website using the 4G network.

WHUD has developed a way to better keep track of their employees, customer calls, and water outages. Each employee is equipped with a tablet that allows the customer to log into the WHUD application. This feature is currently available to the company's workers and management staff. Such applications allow direct communication within

the company from managers to workers. It connects the customers to the workers. As customers call the utility department to report problems, the operator begins to issue alerts to the crews in the field. The alert is then sent to the closest crew to location of the customer. Once the crews arrive at the location they are instructed to update the job information. Once the job information is updated managers know exactly what the crew has found and what machines will need to be sent to the job site. There are many benefits the employees themselves get from this application.

Benefits for employees include: being able to log job site information on to tablets, allowing workers to clock in and clock out. The use of the 4G network allow managers to inform each crew that their work schedule are and what each job involves. Before such 4G networks were available, miscommunications could often occur between management and employees in the field, since not all pertinent information could be logged in a timely manner. Unfortunately, without such networks, some employees might not be given full amount of pay because hours could not be logged while out on the field and there would little information related to time an employee was actually spent at the job site. With 4G, crews are immediately clocked in when the alert is sent through the application and they click to verify that they are on their way. Management was able to track their vehicles through this application as well. This tracking capability allowed managers to know where each truck is and who is driving them to ensure that employees were proper compensated.

WHUD is equipped with its own IT technicians. These technicians work primarily on the servers that transmit information from the call centers to the maintenance crews in order to better serve the community. Such applications through the 4G network allow multiple servers and hardware devices to connect the call centers, managers, and employees in the field. These technicians are on call 24/7 and need to make sure everyone is able to connect in order to allow fast response times.

Working through the 4G network allows great mobility to the infrastructure but requires a lot of upkeep. Technicians are required to update the servers and the application. Updates are required monthly unless any software bugs are found that hinder the use of the application. If bugs are found, the technicians immediately begin to solve the issues. Most issues are fixed within a day, but there has been a period of a 2-day down time. According to a current manager with WHUD, during this 2-day down time customers and employees realized how much the 4G networks and its apps help them in routine operations.

As suggested by interviews conducted by the authors of this chapter, this 2-day downtime was treacherous and possibly dangerous to their work crews. In a particular example, one of the interviewees stated that the 2-day down time was due to a storm that came through the Sumner County Area. This storm disconnected one of the servers for WHUD, eliminating the transmission of information to the employees. Employees could not contact managers. Calls centers were forced to hand-dial every members' work phone, call each crew to determine their locations, and finally put a crew in route to the issue. This task took up to 2 hours as compared to what would take only about 5 minutes when the 4G network was fully operational. The manager stated how relieved management and staff were when the first alert came back through the network. Technicians said that it was one of the worst outages they had seen. Since then there have been IT plans in place incase another outage like this were to happen. Customers benefit from the use of 4G networks being able to connect to their utility department while they complete other tasks outside their homes and offices.

WHUD provides customers with a user-friendly website. On this website, there is a link for frequently asked questions which not only provides responses to the questions, but it provides short videos to some of those questions. In particular, a couple of those frequently asked questions to this company that are accompanied with videos are:

“How do I shut my water off in my house in the case of an emergency?” and “How do I check for a leak?” Being able to learn this information can be essential for a customer. If a customer runs into a problem such as a water line bust in their house they can quickly connect to the WHUD website and turn their water off so they do not have to wait for a service crew. If a water pipe busts in a house it is only minutes before a lot of damage occurs.

Overall, 4G networks have proven to be beneficial to not only individuals but to businesses as well. Such networks offer faster services, the opportunity to build a bigger and better business, as well as the ability to make necessary advancements to keep up with society’s ever changing technology (Elysee, 2015; Latha & Suganthi, 2015)..

FUTURE RESEARCH DIRECTIONS

5G Networks

The future of wireless telecommunications networks may be difficult to predict, but its current growth is well established. Although there are not formal dates have been set yet for the development of Fifth Generation (5G) Networks yet, but a number of companies and organizations have begun establishing their own timelines to anticipate the growth of the impending transition within the industry. It is generally estimated that the timescale for the first 5G networks will be around 2020; however, the useful lifetime for 5G is likely to take time to develop, as it is aimed at providing general connectivity with many applications needing to remain in place for many years. Utility meters, for example remain in place for many years, and the utility companies will not take kindly to having to replace their meters more frequently to follow the cellular technologies.

It is important to understand that the impact of 5G will extend well beyond telecommunications. By connecting people, machines, and things on a massive scale, 5G will facilitate the delivery of personalized healthcare, optimize transportation

logistics, enhance worldwide access to culture and education, and quite possibly virtually revolutionize public services. Before exploring the future of telecommunications, many elements must be considered and the concluding pages of this chapter will cover topics such as standardization, development of new technology, and ultimately the release of much needed spectrum speeds. These elements, among others, will need to be managed closely throughout infrastructure and process development and expertly combined to enable system launch within the required timescale.

To expand upon elements needed to enable future 5G networks, one major consideration will be the release of frequency spectrum. Radio Access Network (RAN) is one wireless network in particular which uses radio frequencies to communicate between any remotely controlled machine (i.e., devices such as mobile phones or computers) and their core networks. RAN includes the same technologies used in base stations and is anticipated to take an estimated six months to reach agreements on the bulk of 5G network RAN requirements.

Globally, strict management will be needed to ensure commonality and reduce the interference between services, especially those operating internationally. Organizations such as the International Telecommunications Union (ITU) will be called on for oversight in this daunting task. Large international meetings called by the World Radio Conference (WRC) are held every four years, with the next scheduled to take place throughout November of 2015 in Geneva, Switzerland (“World Radio Communication Conference,” 2015).

At the World Radio Conference, the main focus for mobile telecommunications is centered on providing additional frequency spectrums for 4G services, seeing as work is not yet sufficiently advanced for determining allocations for 5G. However, by 2019 the WRC anticipates that 5G developments will be sufficient enough to sustain telecommunications initiatives. Although the earliest deployments for 5G may occur around 2020, these will be comparatively limited and its use not

as wide as it is anticipated to be later. Accordingly, the dates for spectrum release for 5G will grow progressively as 5G deployments increase, bandwidth requirements grow, and technology is made available to the consumer (“World Radio Communication Conference,” 2015).

Technology development started shortly after the first 4G deployments. Currently, the most promising advance is multiple input multiple output (MiMo) technology, which uses multiple small antennae to service each individual data stream. Samsung successfully tested advanced MiMo antennae with data speeds at 1 gigabyte per second in May, 2013. The timeline for the research phase can only be broadly bounded and work will be ongoing even after the system enters service, it is anticipated that the basic research and investigations will need to be complete by around 2016 to enable this to feed into the standardization process.

Standardization, just like in any industry, is a key element of the 5G development process whereas the timescales and dates of this activity are integral to the successful deployment of 5G. Standardization of 5G will involve several agencies, of which the 3rd Generation Partnership Project (3GPP), The European Telecommunications Standards Institute (ETSI), Next Generation Mobile Networks (NGMN), and Institute of Electrical and Electronics Engineers (IEEE) are a few. Why are these agencies so important in any standardization effort? As their collective efforts were used to establish the definition of the cellular standard and one of the most important authorities in this arena is 3GPP, so having their collaboration is essential for any standardization effort. Although, with 5G emerging as collaboration of technologies, it is likely to require a number of standards institutions to reciprocate the aggregation in order to make 5G widespread and acceptable to the global economy.

Cost Considerations of 5G

Undoubtedly, global communications reached a point of unprecedented change in both mobile and fixed networks. Each attempts to meet the insatiable demand for data that has been driven by smart phones and tablets. Currently, these devices use both 4G and Wi-Fi radio technologies to access services via both mobile and fixed network cores, but developments in the next generation of wireless communication networks are rapidly moving to commercialization.

Although, it is not possible to know how 5G-network technologies will affect mobile phone and data rates, it should have major impacts on the mobile communication industry. According to a recent article (“A look into the future ...,” 2014), the South Korea’s Minister of Engineering, Science and Technology estimated that private companies will probably spend over US\$300 billion in 5G infrastructure and technology. This coordinated effort is designed to 5G worldwide and the intensity of competition in the industry should be high. Data prices have continuously fallen, from approximately 46 cents per megabyte in 2008 to 2-3 cents in 2014. It is hoped that successful 5G networks would provide 50 gigabytes of data per person per month, a significant improvement in the current offerings of 4G. What will be different? Currently, there are no 5G phones and devices to use the new technology, although manufacturers like Samsung, LG, and HTC are experimenting with new designs. No one knows with certainty what features a 5G phone or device will have. Innovative mobile service providers, companies like Netflix, will have to decide whether they want to make their data available at 5G speeds, so there are many variables affecting the future of mobile technology.

CONCLUSION

Wireless networking has evolved quickly over a very short timeframe. Historically, 2G network focused on real-time audio, 3G focused on data, and 4G has been centered largely on providing relatively high-quality video. The specifics on future network developments are still unclear, and while the issue is mind-boggling and complex, 5G networks will probably usher in an entirely new era all about making connections. 4G wireless networks have forever revolutionized the way people communicate, and the challenges still facing service providers today will likely become advantages under 5G infrastructure. Global implementation is inevitable, with mobile networks estimated to support over 7 trillion connected devices beginning in just a decade. The mobile communications industry is turning towards future innovations that will forever change lifestyles.

KEY TERMS AND DEFINITIONS

e-Discovery: This term refers to all types of electronic information storage (e.g., e-mails,

directories, documents, searches, etc.) that are either targets investigations in which the affected organization need to produce evidence of such transactions. In other cases, information have been mistakenly lost or deleted and managers or employees need to retrieve message-level data.

Multiple Input, Multiple Output (MiMo)

Technology: MiMo, or often referred to as antenna technology, is a term that refers to multiple input, multiple output, which is basically an antenna technology for wireless communications. This technology, multiple antennas are used at both the source (i.e., transmitter) and the destination (i.e., receiver) and the antenna arrays are combined to minimize errors and optimize data speed.

Long Term Evolution (LTE): LTE is a commonly accepted standard for wireless communications for mobile phones based on packet switching. This is an entirely different approach from the circuit-switching approach employed in 3G telecommunications networks.

Radio Access Network (RAN): RAN is one-wireless network in particular which uses radio

frequencies to communicate between any remotely controlled machine, typically mobile phones or computers, and their core networks.

Terminal and Network Heterogeneity:

The next generation wireless networks should be heterogeneous (e.g., consisting of multiple radio access technologies that simultaneously coexisting in the same geographical area). Such heterogeneous wireless networks should consist of mobile terminals of different capabilities (i.e., heterogeneous terminals) that can be used by customers to access network services. Typically, heterogeneous mobile terminals (e.g. single-mode, dual-mode, triple-mode, etc.) use call-blocking and call-dropping capabilities in a cooperative and shared wireless environment.

Worldwide Interoperability for Microwave Access (WiMAX) standard: WiMAX is a global wireless industry coalition created to foster the acceptance and advancement of IEEE 802.16 standards for broadband wireless access (BWA) networks.

Flying Adhoc Networks Concept and Challenges

Kuldeep Singh

Thapar University, India

INTRODUCTION

In case of a calamitous event, when traditional communication methods are out of service or simply not available, in those situations mobile adhoc networks (MANETs) plays an important role in established communication. MANETs employ grounded mobile nodes which are capable to collect information with the help of sensor, camera and other devices. Nodes in MANETs communicate with each other through wireless communication without use of existing infrastructure. The data collected with nodes in MANETs are transmitted to the base station using a multi-hop path. These networks are economical and can be formed in quickly whenever required as they do not require existing infrastructure. MANETs have several application areas such as natural disaster, sensor networks, etc.. But there are some extreme situations (such as flooding, battlefield and rescue operations, etc.) where MANETs cannot be deployed. In those situations, flying ad-hoc networks (FANETs) can play vital role in established communication. FANET is a subclass of MANETs and made up of a swarm of small flying vehicles enable with camera, sensor and GPS system. Swarms of UAVs arrange themselves to communicate with large operational area using wireless network without any centralized device. According to muller (2012) UAVs communicate with each other locally, with base station and also interact with

their environment to get information. FANETs use different types of UAVs based on the various application areas. FANETs employ unmanned aerial vehicle (UAVs), UAV is an aircraft which flies without a pilot. The UAV can manage itself and fly based on preprogrammed flight plans or can be operated using complex dynamic automation systems which are versatile and flexible in implementation (Muller, 2012). FANETs use multi-UAVs to perform operations because of the limitations of a single UAV system such as limited surveillance capability, scalability and flexibility (Bekmezci, 2013). The multi-UAV system has various advantages over single UAVs such as:

- With more number of UAVs, tasks can be parallelized which in turn reduce the completion time of mission. This kind of behavior is very useful for search and rescue applications;
- In case of a single UAV system, whole mission collapse if UAV fails. In multi-UAV systems, nodes can distribute tasks among themselves. Fault tolerance of the network increases with multi-UAVs;
- In multi-UAV environment, heterogeneous UAVs can form a network. It is possible to use capabilities of other UAVs as and when required for task completion. So multi-UAV systems are very advantageous for critical applications.

FANET Applications

Due to various advantages and wide range of application areas FANETs are getting attention from the research community around the globe. Various applications of FANETs are explained and shown in Figure 1:

- **Military Services:** FANET are very useful in military services. Setting up the proper communication system is very difficult in military areas. So FANETs are used for information exchange among soldiers, military headquarters;
- **Security Purpose:** FANET is capable of receiving information quickly. It can be used to collect information for the security purpose of a delegate visiting to a place where no network infrastructure exists;
- **Calamity Administration:** FANET is useful when the existing communication system is damaged due to natural disaster like floods, earthquake, firing, etc. Gathering and sending information in such areas becomes difficult in such situation. FANET provides the necessary communication;
- **Search and Rescue Operations:** FANET can be used to provide a better way to do search and rescue operations such as rescue of hostages (Bekmezci, 2013). Sometimes in extreme situations, cellular networks get damaged. FANETs provide better rescue services in such conditions by sending periodic updates to other locations;
- **In Sensor Networks:** Different sensor devices can be used to collect data to do daily functions like weather forecasting, terrestrial movement tracking, etc. FANETs can approach to any remote location without difficulties;
- **Location Aware Services:** FANETs can be used in many services like forwarding calls to any location, travel guide for passengers, identify information regarding specific location;

Figure 1. FANET applications

- **City Architecture Planning:** FANETs are designed to focus emergency services and military applications, but FANETs can be used in the development of a city. FANETs can be used to develop city architecture. UAVs can help to plan and manage architectures of roads and buildings in a city based on its geographical location;
- **Law Enforcement:** UAVs capabilities can be utilized for law and order of a city. FANETs can provide surveillance facilities on the roads and the streets of a city in situations of riots and curfew, FANETs can collect video recordings and images to support police or soldiers to control the situation. Later images and videos can be used as evidence in the court against the accused.

BACKGROUND

The term FANETs is first introduced by the Michael Muller in 2012. Before FANETs, MANETs were the best way to communicate in emergency situations, as they can be established quickly, easy to deploy and economical. MANETs employ grounded moving nodes, which are capable to communicate each other without using pre-existing infrastructure. These networks are also known as grounded ad-hoc networks. MANETs have some limitations which force researchers find a better solution for those situations where MANETs cannot be useful. Researcher's wants to use the capability of UAV in ad-hoc network, so they developed single large UAV guided ad-hoc network. In this network, UAV collects the information and passes it to the grounded, moving nodes, which help grounded nodes to perform task efficiently. But single UAV based ad-hoc network cannot accomplish all the tasks by itself. Finally, research community came up with an idea of using multiple UAV to create ad-hoc networks. The idea behind the FANET is to overcome with the limitations of grounded ad-hoc network by

using the advantages of multiple UAVs together to perform tasks. In FANETs, a swarm of UAVs established communication link between them. They collect information and transfer it to the grounded nodes with the help of established links. Due to the wide range of FANETs applications, the research community is actively participating to formulate efficient infrastructure, routing and security mechanisms for FANETs.

FANET Concept

FANETs are basically adhoc network created by a group of UAVs, which is a new family of adhoc networks. Single UAV guided adhoc networks have some limitations as single UAV cannot collect information from the whole geographical area of the operation independently. So, multiple UAVs are used to form adhoc networks called FANET. As, FANETs uses multiple UAVs, so they improve scalability and flexibility ad-hoc networks. Each UAV is equipped with sensors, on-board monitor, GPS receiver and autopilot. The UAVs are fixed wing aircrafts with autopilot, capable of flying up to 12 m/s and up to 3 km/s in emergency situations. UAVs are available in different sizes for different applications. Different sizes of UAVs are: Micro UAVs, Low altitude and low endurance UAVs and high altitude and high endurance UAVs. The swarm of UAVs communicates among themselves and with the ground station. There are two types of communication:

- **UAV to UAV Communication:** In UAV to UAV communication, UAVs communicate with each other to complete the allocated task. Two UAVs can either directly communicate or through other UAVs. To communicate indirectly using multiple hops, a communication path is decided based on different routing strategies like reactive, proactive and hybrid routing. UAVs can have either short range or long range communication; it depends on requiring data transfer rate;

- **UAV to Ground Station Communication:** In UAV to ground station communication, UAVs connect to the ground stations to provide or receive information about various operations. Ground stations are basically known as base stations that instruct UAVs for various tasks.

Flying nodes have very high mobility and topological changes, so existing solutions of MANETs cannot be directly applied to FANETs. To formulate solutions for FANETs, either existing solutions can be modified or new techniques can be formulated. To establish communication between nodes, various routing protocols found in literature. These protocols are categorized as follows:

- **Proactive Routing Protocol:** In these protocols, each and every node in the network shares its routing information from its routing table at regular time interval which is used by the other nodes to identify the path for destination nodes and make the map of the whole network. The big advantage of these protocols is that these protocols take a very short time period to get the path to the destination. But, it costs very much bandwidth consumption to update the information within a short period of time thorough which it maintains maps of the whole network. There are several proposed algorithms under this category like WRP, DSDV and OLSR (Singh & Verma, 2014);
- **Reactive Routing Protocol:** Reactive routing protocols are on-demand protocols, they build path whenever required by network nodes. The Reactive protocols do not broadcast their routing table information in regular time interval. They broadcast their routing information only when it is needed. Therefore, they minimize the use of network bandwidth. But, due to the reactive nature, there is a disadvantage to

these types of routing algorithms, End to End delay of packet delivery is increased as compared to proactive protocols. They also take more time to select an immediate node to transfer the data packet because of the dynamic network topology. Reactive protocols are less likely to use in applications in a dynamic environment. Many algorithms are proposed under this category like AODV, DSR and ABR;

- **Hybrid Routing Protocol:** Hybrid protocols are a combination of both proactive and reactive protocols. These protocols are designed to minimize the overhead, which occurs in both types of protocols (reactive and proactive). But, the protocols under this category are not suitable for large networks having more than hundred nodes because of large overlapping of zones like ZRP.

FANET Design Considerations

Due to distinctive features of FANET, it requires different design considerations than traditional ad-hoc networks. Here we discuss major design considerations: adaptability, latency, mobility, UAV platform constraints, scalability and bandwidth requirement:

- **Adaptability:** FANET nodes are highly mobile in nature. Due to this behavior of nodes, they keep on changing their location (Lin, Sun, Li & Yang, 2012). The routes between UAVs keep changing and distance between them is also not constant. Another problem is UAV failure that decreases the number of UAVs in networks. So the FANET design should consider these UAV failures and frequent path changes. The overall performance of the network depends on the adaptability on these path changes and topology changes;
- **Latency:** Latency is considered as one of the main design requirement of any net-

work. Latency is basically an application dependent factor. For real time applications of FANET like search and rescue operations, military application latency should be low for transferring information. These are time bound applications. For non-time critical applications such as city architecture, planning etc. the latency factor can be less compromised (Rosati et al., 2013);

- **Mobility:** Mobility of UAVs plays an important role in the performance of FANETs. There are several movement patterns for an adhoc network node. Moving pattern can be for group or individual node. It is very crucial to identify that which moving pattern of UAVs will be suitable to complete task effectively and in time bound manner;
- **UAV Platform Constraints:** UAVs used in FANETs have limited payload capability, so they have certain constraints. Hardware weight affects the performance of UAVs, light payload increases the endurance. So, UAV with a lighter payload have the scope for additional resources such as sensors and other peripheral devices. Another limitation faced by the UAVs used in FANETs is space limitation;
- **Scalability:** Multi-UAVs can enhance the overall performance of network as compared to single UAV systems. Performance is enhanced by increasing the number of UAVs in the network. Higher the number of UAVs, faster will be the task completion and more reliable will be the network. Scalability is an important factor for time dependent applications;
- **Bandwidth Requirement:** In every FANET application, UAVs collect data from environment with the help of cameras and different sensors, collected data is transmitted to ground base through multipath route. Data collected in applications such as monitoring, rescue, surveillance and battlefield are mainly higher resolution video, images and audio (Rosati et al., 2014)..

Also captured data is crucial and required to be transmitted with strict delay bound. So FANETs require high bandwidth resource to complete operation efficiently within time bound.

FANET CHALLENGES

FANET is the member of MANET family. FANET faces some additional challenges along with already existing challenges in MANET family due to its high node speed, high topology changes and mobility models. Based on the finding of literature review, following are the areas identified that require significant research to be done (see Table 1):

- **Routing:** Routing in FANETs is different from other adhoc networks family. Node movement is relatively very high in FANETs. So the topology changes very frequently. One of the biggest challenges is to develop an efficient routing algorithm that not only able to work with high mobility nodes, but should be quick to update its routing table frequently as the topology changes (Sahingoz, 2014);
- **Security:** Ensuring confidentiality, availability and Integrity of information during the communication between UAV to UAV communication and UAV to ground node communication is one of the major issues faced by FANETs (Yap et al., 2015). Due to lack of physical security node compromise becomes easy in FANETs. Trust Management among nodes is another challenge due to high topology changes. Nodes join and leave the network very frequently. Secure routing is another point of concern in FANET;
- **Quality of Service (QoS):** In FANETs UAVs transmit data includes audio, video, images, text, GPS locations, etc. To transfer such data FANETs should have a good

quality of service with less delays and error rates (Yanmaz et al., 2010);

- **UAV Mobility and Placement:** The placement of UAVs at appropriate location is one of the major research concerns in FANETs. UAVs of different capacity and capability are used for different purpose. Mini-UAVs are meant for carrying fewer payloads, like a thermal camera, single radar, camera, image sensor, *etc.* So, this is an open challenge to optimize the UAV placement to diminish energy feeding when the retrieved information is taking more time;
- **Network Scalability:** Single UAV system can perform limited tasks. To perform tasks quickly and efficiently, collection of UAVs is required. This motivated the concept of multi-UAV based system (Saleem et al., 2015). Sometimes if during the task few UAVs are out of the network due to power or some technical reason than it is required to add some new UAVs in the network to complete tasks efficiently. FANET algorithms should be designed in such a way so that they will be flexible to add any number of UAVs;
- **Reliable Data Delivery:** FANET applications transfer very important information in different applications, which required to be delivered in time bound manner. So the reliability of the network should be very high. Reliability should be defined with the criticality of data.

FUTURE RESEARCH DIRECTIONS

FANETs are getting more attention due to their capabilities in various situations. These networks have the additional advantages of the traditional adhoc networks because they use flying agents to collect and transmit the information in the operation areas. Due to high speed of UAVs, these networks are highly dynamic and have high topology changes. To support data transition with

Table 1. Common attacks of FANET

FANET Security Layer	Attacks
Multilayer Attacks	DOS, Impersonation, Replay, MIMA
Physical Layer	Intervention, Jamming, Snooping
Data Link Layer	Disruption MAC (802.11), bandwidth stealing, traffic monitoring, WEP weakness
Network layer	Black Hole, Link Spoofing, Worm-hole, Route tracking, Message fabrication, Byzantine
Transport layer	Session hijacking, SYN Flooding
Application layer	Repudiation, data corruption

dynamicity of these networks, an efficient routing scheme is required. So, developing appropriate routing protocols is one of the inspiring areas of research. Another explorative field of research in FANETs is the appropriate size of flying node, its power consumption, range covered by the node and speed of flying node. Along with communication and infrastructure needs, security of FANETs is also grabbing attention of researchers because FANETs carry sensitive and confidential information of critical application area. Security of flying nodes, trust management within nodes and secure routing are significantly important areas of research in FANETs.

CONCLUSION

The capabilities and applications of FANETs are very prominent in complex areas. UAVs coordinate and communicate with each other to perform complex task efficiently and faster where ground communication does not work. The swarm of UAVs communicating with each other without the use of pre-existing infrastructure is termed as flying adhoc network. Aim of FANETs is to provide fast, reliable and secure communication services in the various application areas. Nodes

in FANETs are highly mobile in nature and topology changes very frequent. Managing UAVs in FANET is a very challenging task.

In this article, the basic concept of FANET, various applications and challenges are explained. This article aims to motivate the research community to come up with various solutions to the challenges faced in FANETs.

KEY TERMS AND DEFINITIONS

ADHOC Networks: An adhoc network is a local network that is created spontaneously to perform a specific task. Instead of coordinating

with base station, nodes forward packets with each other.

FANET: FANET is a subclass of MANETs and made up of a swarm of small flying vehicles enable with camera, sensor and GPS system.

MANET: A mobile ad hoc network (MANET) is self-organizing, infrastructure less network of mobile nodes connected without any wired connections.

UAV: An unmanned aerial vehicle (UAV) is an aircraft without any onboard human pilot. UAVs can be controlled by either ground pilots or by pre-programmed software.

M

Health Wearables Turn to Fashion

Lambert Spaanenborg
Comoray AB, Sweden

INTRODUCTION

In the early years of manned space exploration, it is observed that astronauts easily lose a sense of time. Consequently they forget to eat in time and are not constantly fit to operate. From the need to monitor the physical condition of astronauts during travel, it became customary to equip their clothing with health sensors (Soller, 2002). One can see this as an early instance of health tele-monitoring.

These measures originate from the customary monitoring of test pilots to find the effect of extreme flight situations on the human body. But in space travel, the monitoring was not just performed during a couple of minutes but routinely for weeks or even months. This has been extended to other situations where a human pilot is confronted with extreme, potentially life-endangering situations, such as car racing. In all such situations, the clothing can be rigged with a wired network of a fixed-design sensory network and connected to a single control room (Jafari, 2006).

With the advance of microelectronics, a potential consumer market is opening. Mobile Health (m-health) is a technical challenge at the crossroads between personal fitness and hospitalization costs. Lack of exercise and/or bad nutrition undermines health and brings diseases such as heart failure and diabetes that can be hardly cured once become easily noticeable. Ultimately hospitalization cannot be avoided. Such stays will be regular and lengthy while surgery will be part of the service.

Tele monitoring is currently tested to reduce the length of hospital stays and the number of check-up visits by providing post-surgery health monitoring at home over remote links. On the other hand, a proper life style can delay the advent of diseases or even preclude their coming. The

current research interest is to collect data on large groups of people to identify risk groups. Then persons with a high risk can be identified and will receive pre-screening. Consequently, organizing special heart failure and diabetes clinics reduce hospital costs.

People do fitness in order to stay in shape. Usually it requires a regular doctor visit to ensure that the training does not damage the person's health. Self-quantification allows the person to play doctor himself, making the health check available constantly. There are little more health-related products in the common house than the thermometer, scales, cough drops and the medicine cabinet. Tele-monitoring requires additional 2,500 Euro worth of equipment to be installed in the house of the patient. This price tag cannot be tolerated for the average household, but the insurance may pick up the tab for the approved patient. Usually health-monitoring equipment is found in clinics and fitness clubs, where many people can take advantage. The modern equivalent is the 'kiosk': a dedicated booth in public places in and outside hospitals that can be visited at will and provides equipment in a direct link to the hospital infrastructure.

M-health is the next step to bring affordable healthcare in the home, and to any place where a person goes. It can be attached as simple gadgets or be integrated as plaster, garment or ornament. But it will only be more than a consumer gadget, when it (a) gets medical quality information and (b) communicates that information to the medical world, if desired and necessary. Further into the future, but not that far away, is the caring home, where healthy dwellers are measured to ensure that any health-endangering conditions can be detected and brought to the attention of a physician in time.

DOI: 10.4018/978-1-5225-2255-3.ch531

According to the World Health Organization (WHO) such precautions can reduce the amount of visits to the hospital by 90% (WHO, 2011)!

In the following, the history of wearable devices is outlined, coming from m-health to e-fashion. Then the state-of-the-art of oximetry technology is discussed, leading to an overview of trends in consumer health technology, leading to conclusions on their role in personal life-style improvement.

BACKGROUND

The m-health arena has started from a replacement market. Here Apps are administrative systems where the end-user is logging available data as provided from other sources. Examples are body temperature from a thermometer, calories from the food wrapper and body weight from bathroom scales. Such products do not provide more than a simple agenda for logging and many products share a lack of enthusiasm in the market.

The arena is growing in interest. Here electronic devices are integrated into common products, like bracelets, plasters and chains to provide single measurements on the body. A number of them still require additional handling. For instance, the usual glucose meter requires a blood sample to be taken and prepared for a special portable device. There is a tendency to become less invasive using intraperitoneal sensing (vanDijk, 2015), but non-invasive would be even better. A nice example is the gradual miniaturization of the pulse oximeter, which has gradually decreased in size while moving from the hospital to the clinic, and which will likely become as common as the thermometer in the very near future.

The forerunner in the pursuit of personal health is the fitness market. Apps like RunKeeper and EndoMondo have received a lot of attention for the creation of social health networks. Gradually they will make inroads to electronically capture health data. The widely accepted Cooper test is based on the correlation between the VO₂max and

the distance covered in a 12 minute run (Cooper, 1969). Hence it indicates fitness by the ability of the body to use oxygen while running. This can nowadays be monitored with a strapped-on oximeter. Another requirement for fitness training is heart rate or ECG monitoring. Here we find an exponentially increasing amount of wearables with more or less success. Here continuous logging of an oximeter is an attractive alternative.

The typical health service needs first of all to provide a regular check like yearly done by the family doctor, i.e. looking at health in general. This can be seen as the Mc.Luhan effect on health provision, where instead of having the doctor come for a yearly visit, ICT will allow a regular check-up which can be viewed by the doctor at any time and any place. In other words, the players in the health service game are swapping places. The every Tom, Dick and Harry are not really concerned with health till they get sick. They do not want to be treated as patients and are therefore not susceptible to public information provision. When health gets their interest, it is usually through a desire to stay forever young. Alternatively, when they have been to the hospital, the main interest is to get back into shape.

Beyond the Thermometer

The exemplary device for electronification of health equipment is the pulse oximeter, originally created to support the anesthetist in his work. This device measures the degree of perfusion and thereby certifies the distribution of anesthetics. Then Aoyagi notes that a longer observation shows also the pulsating period of the blood pulse. This opens the door for non-invasive measuring more health parameters _ like cardiac functions showing atrial fibrillation and stress _ for everyday use through the single photoplethysmographic (PPG) signal. Wieringa (2007) re-calls the evolution of the thermometer into a common household product and then foretells that the modern oximeter will revolutionize personal healthcare in a similar way.

The early pulse oximeter is based on the comparison of reflected light in the infrared band (showing oxydized hemoglobine) and the red band (showing de-oxydized hemoglobine). As shown by Mendelson from the Worchester Institute of Technology over the last 2 decades, the same results can be found by looking at reflections in the green and the red band (Scully, 2012). Especially the green band is interesting, as it seems less sensitive to muscle movements in the body. The principle of operation transforms the intensities of the reflected light into a time series on which filtering and Fourier transform brings the energy-frequency map where the characteristic cardiac parameters can be found. It requires top-notch filter design to boost the signal enough while reducing the noise level.

The use of reflective light to achieve pulse oximeter functionality is largely caused by the light transport through the skin tissue, where the effective intensity signal is reduced by a factor 50 through scattering and dispersion. As Mendelson has demonstrated in a number of careful experiments, the smartphone image provides enough information to measure cardiac values that are less than 5% different from hospital lab equipment. But further tuning was required to allow for a real-time smartphone implementation. Current offers in the market (the heart rate, sleep and stress monitors) aim for real-time while compromising accuracy and functionality. The next generation will support nutrition, life style and living environment in their influence on the bodily condition from a single smartphone: Like a modern Internet connected thermometer!

Wearable

The ideal is non-invasive measurements and of course it has taken a long time to reach that ideal. The critical aspect of its breakthrough is the movement of the phone while measuring. Especially when forcibly trying to keep it still, every hand-held device will be subject to a degree of jitter. When the exposure time for measurement

exceeds a couple of seconds, other spastic movements will come into play. The mixed influence of interfaces between (largely watery) transmission media and sensor movement sets the lower limit to the achievable precision and accuracy. This is not new by nature. Single-point measurements are generally acknowledged as being impossible to stabilize. The commonly accepted solution is the multi-point measurement. The medical ECG measurement takes a minimum of 8 probes to achieve a reliable result, i.e. it can detect handling errors and comes with a useful error margin.

In search for the successor of the smart phone, the smart watch is on the horizon. Typically they are to be worn on the body, and are in competition with similarly wearable gadgets such as the earring or the tracking shoe. The early smart watch has limited health information, mostly limited to heart rate, and more fitness data collection capability. It has a large display to allow entering and reading data and a large size to optimize energy harvesting to increase battery lifetime.

The alternative of reflective vision technology uses the accelerator. Where movement distorts the PPG signal, the accelerator measures the motion directly and must be filtered to find the heart rate (Hernandez, 2015). The BioPhone claims a similar accuracy, even when the smart phone is handled loosely. As the outcome of the measurements depends on the body part used for sourcing the signal, they can also be used in combination with other accessories into a local health network.

The Body Area Network

Having garment equipped with a sensory system provides the basis for multiple probes. The hospital equipment uses these strobes to collect data centrally and continuously. By subsequent signal analysis, time correlation identifies the important features. In the garment, this spaghetti wiring is organised and woven into the fabric (Jafari, 2006). Moreover, the probes are intelligent by itself making for a distribution of functionality over a medical embedded network.

The Body-Area-Network (BAN) is not a new concept (Yang, 2006). In the usual sense, the sensors are connected with a director, a gateway that collects and analyzes data. The smart phone can take this role as director. At least it may bring the data from the typical short distance of the BAN to the large distance of the wireless telephone network. The added advantage is that all computationally, energetically and spatially intensive tasks can be performed on the phone, releasing such demands from the network.

A typical BAN example is the Clothing+ sportswear. It provides a number of sensors in a sport suit, which can be collected over a close-by mobile product, such as an E-Pad. It was invented to help polar adventurers to survive the extreme conditions under deep-winter conditions, and can easily be extended to the E-sports market where the amateur athlete's life may already be threatened under less extreme weather conditions. For instance, T.Ware adds support for tracking suits in general, but especially for people where the added sensors give a clear added experience, such as for autistic children.

MAIN FOCUS OF THE ARTICLE

The PPG technique was originally published by Hertzman in 1938 and became popular around 2000 for perfusion measurements to aid anesthetic monitoring. (Forstner (1988) gives a good breakdown of the time in between). The latest developments have confirmed that PPG brings accurate non-invasive acquisition of major physiological parameters. Where PPG signals are extracted from the absorption of light in blood, devices come in two different flavors. On thin body parts, such as the tongue or earlobe, light will be transmitted from one side and sensed on the other. When the body part is too thick, light source and sensor are at the same side. The latter, light reflective device is the most popular for reason of the ease of construction.

The earliest detection of decreased blood oxygenation is by the skin color shift towards blue (also named cyanosis). Together with a weakening pulse, this was known (especially to mountain climbers) as a life threatening condition that requires immediate attention. Hard to perform manually over a longer period, a number of opto-electronic devices have been attempted. The major breakthrough is the observation by Aoyagi in 1974 that by the pulsatile nature of blood flow through the arteries the contribution of arterial absorbance can be distinguished from tissue absorbance components. From there, pulse oximetry rapidly spread as a simple, bedside technique to monitor heart rate and arterial oxygen saturation.

Wieringa (2005) remarked that pulse oximetry has changed many clinical routines and made the analogy with the influence of thermometry three centuries earlier. From the historical development of thermal cameras in extension of the conventional thermometer, he claims room for remote sensing in photoplethysmography over the coming years. Literature shows that he may have been right.

Measuring by Reflective Light

The principle of the oximeter is based on the pulsatile nature of blood flow. The high frequency reaction of the light on the capillary blood shows as color, while the intensity changes in value with the flow. The flow of blood is then found as variations in the observed color and intensity. The quantification of the blob is done by arbitrarily averaging an arbitrary number of pixels. So we have two sources of information: the intensity and the color as energy and frequency in the spectrum. This seems to imply the use of Fast Fourier Transform (FFT) to determine the location of the pulses in the energy-frequency plot. The visual spectrum lies between 200 and 600 nm, i.e. in the TeraHertz region. The physiological parameters of direct interest are at 1 Hz (heart rate with the 1st harmonic at 2 Hz) and the respiration rate between 0.1 and 0.16 Hz (with harmonics at 0.2, 0.3 and 0.4 Hz).

These frequencies are relatively easy to determine, but are not so easily distinguished because they change considerably under the exercise regime. (When the heart rate goes up, also the respiration rate increases and comes around the resting values of the heart rate. This seems to preclude the use of fixed-band filters (Nakajima, 1996)). The classical oximeter approach is based on the Beer-Lambert law on absorption, which states that the absorption at a given wavelength is the product of the absorbency, the concentration and the path length. How this can be interpreted has been regularly subject of discussion. It seems that the absolute value needs calibration for every new person. Also the digital signal processing can cause 5 – 10% numerical accuracy issues when done improperly.

The clinical approach for raising the accuracy for the computation is the ‘ratio of ratios’. For instance, arterial oxygenation can be found from the ratio between peak-to-peak amplitudes at a minimal of two different wavelengths. Using a white LED as illumination source, the popular color for the PPG measurement is green. Jonathan (2010) claims that blue and red are also usable, but the signal strength is highly position specific. However, it usually pays to see the emergence of low blood oxygen levels (hypoxemia) ahead of time. For this, it is useful to look at the red and infrared bands. Scully (2012) uses also green for the heart rate, but the SpO₂ is computed from the red and the blue where the blue band is the reference for the infrared wavelength in the traditional pulse oximeter.

Pulse Oximetry

The classical oximeter means to determine the arterial oxygen saturation (SaO₂) by measuring differences in the visible and near infrared absorbance effects of fully oxygenated and deoxygenated arterial blood. They have largely replaced clinical blood gas analyzers that can only take intermittent values from blood samples. It provided a clear

innovation, freeing access to the machine from the operating room / critical care unit to enter any ward in the hospital.

The early oximeter is non-pulsatile using multiple wavelengths, where one (805 nm in the near infrared) is used as a reference to eliminate the effect of tissue absorption and skin pigmentation, while the other (650 nm in the blue band) determines the value. The earlobe was a popular location as it is easily accessible, while being painless and bloodless in the reference mode (Huei, 2011). The pulse oximeter exploits the pulsed nature of the photoplethysmogram to bring the wavelength needs to a single one.

Mendelson (1992) gives such a historical background together with an overview of practical problems, as felt in 1990. This overview lists also nicely what can be potentially achieved by technological improvements. Typically it mentions the measurement of carbon monoxide, as neglecting this effect leads to an overestimation of SaO₂ in smokers, lung patients or (more general) people with a limited supply of oxygen. It has been attempted to exploit the PPG technology through non-contact measures, say, through a camera in near infrared. As discussed in (Wu, 2003), it provides clear vision on venous issue, supporting the need to determine perfusion in a general sense. The paper mentions vein insufficiency and thrombosis. However, the strong disturbance of tissue reflection brings the arterial information to less than 2% of the total amplitude.

Over the past years, there is an increasing interest in non-invasive PPG measurement using commercial mobile devices, such as (Web) cameras and mobile telephones. The early literature claims the need for HD devices; the later assumes this to be always available. This shows a move away from the original anesthetic measurement (to provide feedback on the quality of the blood flow) to the cardiac monitor on a consumer product. Or, in terms of technology, it exemplifies a move from understanding the PPG waveform to implementing digital signal processing. In that sense Shelley is

still waiting for an answer (Shelley, 2007), but we can applaud the systematic research by Mendelson that opened many doors for further developments.

FUTURE RESEARCH DIRECTIONS

Along the historical development of the smart phone, it is reasonable to assume that the first steps in m-health will be to serve geo- and socio-positioning. Geo-positioning helps persons to be found; a function to position an object will probably require a keyboard and therefore a phone. Socio-positioning will identify persons of the same social community, for instance having the same original brand of clothing. Because of a lack of active functionality, this all appears like a gadget with little added value, especially compared to the smart phone.

The above distinction becomes more meaningful in sensory networks. A simple measurement will not only vary in time, but also in geo-location. Moreover, the measurable value will vary. For instance, blood pressure depends on the location on the body and on the position of the body. Hence, conclusive values do not result from averaging a series but require an intelligent model. A typical configuration appears in fashion where multiple sensors for redundant health factors are found in free network composition. Problems are even more complex with reference to socio-positioning.

The Future in Fashion

Fashion is clothing with the artful expression of individuality. It can be coarsely subdivided into couture, commercial and catalogue while stating the cost of acquisition, or into factory, office, leisure, athletic (and so on) while stating the current place and activity. The latter is interesting as m-health devices can measure either the body or the environment in its influence to the body. The former is a balance between luxury and commodity. Though m-health is targeted for the mass-market, Apple (with the i-watch) and Misfit

(Fossil since 2015) show that exclusive DESIGN is still part of reality.

Fashion is typically a physical interface. It guards the body against dust and cold. Wearing a heavy coat is not ideal to keep the sun out, while a raincoat will not give enough protection against the freezing rain that lashes the pedestrian. The importance of embedded sensors will be to activate the interface, i.e. to adapt the nature of the clothing to the potential danger coming from the outside. An early example is the 'climate dress' from Diffus. Similarly, the 'Aegis Parka' from Nieuwe Heren, a design bureau in Utrecht (The Netherlands), measures the common urban pollutants (NH₃, NO_x, alcohol, benzene, smoke and CO₂) and shows the relative threat by the illumination of an LED display.

The degree of an environmental threat is given by the apparent lack of protection. To determine that requires body measurements also. For instance, when the atmosphere contains a high degree of CO₂ and the blood of the person who wears this cloth has a high degree of CO₂ then there is a good reason to assume that the health of the person is in danger. When the body also shows a lack of balance, there is a good reason for alarms. An extensive discussion of the current offering and listing of active players is given in (Florea, 2012).

The Future in Intelligence

Where the body is a complex physical system, there are many ways to measure and model it. The preferred way for measurement is non-invasive, as many do not enjoy forced bodily access. This needs medical processes to be available outside the body, like through the skin, via a cavity or by fluids leaving the body. The use of substances naturally leaving the body, like hairs or urine, works similarly to where samples are taken out of the body. The modern alternative is the subdermal sensor implant, where likewise substances need to be delivered to the body. A suitable short-distance wireless connection

A mobile device brings application issues. The easy solution is to create a detachable add-on, such as a thimble, that can be ideally fixed at the right location. The alternative is an attachable product, like a watch or an earring, but this will usually require an additional phone to connect to the outside world. The advantage of the specialized part is that it is designed for a specific parameter, while the disadvantage is that it cannot be programmed for other parameters. This extends naturally to the “Internet of Things”.

In healthcare, security and dependability are required for all thinkable reasons. Hence the demands on the models seem almost crushing. However, functional redundancy alleviates (if not even removes) that burden. The key to all this is ‘deep learning’. A neural network extracts information by correlation; deep learning adds modularity and similar methods of structural composition that avoid the problems of unstructured, large networks. The immense variability of human bodies makes it hard to prepare the learning set.

CONCLUSION

The smart-watch is entering the health market with a fitness proposition, while the smart-phone is keeping strong for vital health. More specialized medical applications are looking for room in the gadget market. Such things become increasingly complex and fashionable.

A typical sexy device is the Vital Signs Camera, launched in early 2012 by Philips as app on an iPad. It measures heart rate from skin coloring and breathing from chest movements by the tablet’s front-facing camera. More experimental is the laser-based blood flow management, where model-based matching helps to achieve medical accuracy in single-probe ECG measurement. As pointed out by Spaanenburg (2010), this opens the door to ad-hoc sensor clouds where health sensors from the environment and those on the body co-operate to bring guidance for life style. Such developments enable personal health monitoring as an Internet of Wearables.

KEY TERMS AND DEFINITIONS

Body-Area-Network: A wireless network of wearable computing devices.

EHealth: The use of electronic processes and communication for healthcare practice.

mHealth: An abbreviation for mobile health, the use of mobile devices for medicine and public health.

Perfusion: The body process delivering capillary blood in its biological tissue.

Photoplethysmography: The use of a pulse oximeter to illuminates the skin and measure changes in light absorption.

PPG: Signal is the photoplethysmographical time-series that is extracted by an oximeter on basis of light reflection on the skin.

Pulse Oximetry: A non-invasive method for measuring a patient's O₂ saturation.

Quantified Self: A movement to incorporate data acquisition technology for health in aspects of a person's daily life.

Reflective Light: Visual light that is sensed from the reflection on the skin.

Smart Phone: A mobile phone with more advanced capability than basic feature phones, such as a vision sensor.

Smart Watch: A wristwatch that at least monitors cardiac effects.

Spectroscopy: Delivers the absorption frequency to indicate the presence and amount of matter.

Wearable Technology: Comprises clothing and accessories incorporating computer and advanced electronic technologies. Meant for the consumer market, it has a clear aesthetic, say fashionable, aspect.

M

Human Psychomotor Performance Under the Exposure to Mobile Phones–Like Electromagnetic Fields

Giuseppe Curcio

University of L'Aquila, Italy

INTRODUCTION

At the present time the great majority of human beings on the planet are directly or indirectly exposed to the electromagnetic fields (EMFs) emitted by mobile phones, base stations, as well as other types of wireless communication technologies. Moreover, to date for the first time ever it can be affirmed that there are more mobile devices in the world than living people: if we look at GSMA's real-time tracker (June 2016), the number of mobile devices is assessed to be more than 7.75 billion, while the total world population is estimated to be around 7.3 billion (US Census Bureau, June 2016). Such repentine increase in number of mobile phones has induced a growing interest toward possible health effects in human beings, bringing also the World Health Organization (WHO) to open a health topic on this issue.

Since a discrete amount of radiofrequency (RF) electromagnetic fields (EMFs) emitted by mobile phones is transmitted through the skull and can reach the brain, it is possible to hypothesize a physiological influence of these low level RF EMFs on human cerebral activity, and, consequently, a potential influence on cognitive and behavioural performance. In the last 20 years a number of studies have assessed several aspects of human performance: vigilance and attention (divided, selective, and focused), perception, learning, short-term and working memory, spatial and verbal recognition, decision making. All these studies have been repeatedly reviewed (e.g. Kwon and Hämäläinen, 2011) and metaanalyzed (e.g., Valentini et al., 2010). And the scientific interest

DOI: 10.4018/978-1-5225-2255-3.ch532

still continues, since that only in the last 5 years (2011-2015) several new papers have been published (Ofstedal et al., 2016). Thus, the present entry will focus on volunteer studies (i.e. experimental studies with volunteer human individuals) and is intended as an updating of a previous critical review of literature (Valentini and Curcio, 2015). Most experimental studies with RF-EMFs exposure have been conducted as laboratory studies. Within each laboratory study, the entry will report only cognitive and psychomotor effects of mobile phone-like EMFs. In different studies, each of these effects have been tested through different tests and tasks, both administered by a computer and in a paper-and-pencil version. Usually in this kind of literature measures of speed (i.e., the time needed to accomplish the requested activity) or accuracy (i.e., the number of correct responses to the task or, conversely, the number of errors or absence of response to a task) have been considered as dependent variables.

BACKGROUND

Most of the included studies entail mobile phone-like signals or base station-like signals as well as other types of EM signals. This review will focus on experimental provocation studies with human volunteers, most of them being carried out as laboratory studies. Only laboratory studies focused on cognitive and psychomotor effects of mobile phone-like EMFs emissions will be taken into consideration. Here, only studies published in the last 20 years and focusing on mobile phone-like

emissions will be considered as relevant. To this respect, we will also provide a qualitative overview of the most recent studies published up to 2015.

Pioneer attempt to study human psychomotor performance was undertaken by Koivisto et al. (2000) and Krause et al. (2000) at the University of Turku (Finland). Most current relevant contributions originate from several scholars distributed across different continents. Particular methodological improvements have been proposed by Curcio et al. (2004, 2008) at the Sapienza University of Rome (Italy) and by Regel et al. (2007 a,b) at the University of Zurich (Switzerland), while enlarged sample sizes have been recently studied by Keetley et al. (2006) and Hamblin et al. (2006) at Swinburne University (Australia). In addition, important attempts of replications were performed by Russo et al. (2006) at University of Essex (UK), and by Haaraala et al. (2007) at the University of Turku (Finland).

As said in a previous review (Valentini and Curcio, 2015) also in this case it is due that several studies reported here were aimed at investigating also brain neurophysiology (with Electroencephalography-EEG, Event-Related Potentials-ERPs, Event-Related Synchronization/Desynchronization-ERS/ERD, Transcranial Magnetic Stimulation-TMS, Magnetoencephalography-MEG) or metabolism (by means of Positron Emission Tomography-PET, functional Magnetic Resonance Imaging-fMRI, functional Near Infrared Spectroscopy-fNIRS); however, only concomitant cognitive and attentional measures will be presented and examined. In particular, we will discuss specifically those outcomes related to speed of motor responses (time needed to complete the trial). This choice is substantiated by the fact that most of studies reporting an effect of RF EMFs observed a significant reduction of reaction times during or after the active exposure, while only a few of them showed effects on accuracy, effects that disappeared when highly conservative post hoc statistical tests were applied. Moreover, the choice is also supported by the hypothesis that RF EMFs may act as modulators of cortical excit-

ability (e.g., Ferreri et al., 2006), which in turn would influence the most sensitive psychomotor function, i.e. motor reaction times to external sensory stimuli.

SCIENTIFIC KNOWLEDGE ABOUT MOBILE PHONE INFLUENCE ON HUMAN PSYCHOMOTOR PERFORMANCE

It is known that volunteer studies are experimental provocation studies with human volunteers; with respect to observational studies, they allow to accurately control some exposure factors that may influence the outcome (as, for example, the exposure characteristics). However, all experimental human studies aimed at exploring transient and relatively mild effects of MP exposure ever respect ethical aspects using exposures that do not exceed the maximal permissible levels defined by ICNIRP (1998) and currently under continuous revision. Considered these limitations, most experimental studies with RF exposure were laboratory studies, but some observational studies also do exist: in these limited cases exposures were administered within a real life situation (such as at work or home). Control of exposure and other potential confounding factors are usually a greater challenge in observational studies than in laboratory provocation studies.

Here, it is provided an updated outlook of laboratory research (up to year 2015). Literature selection criteria and studies endpoints are based on two recent scientific contributions (Valentini et al., 2010; Valentini and Curcio, 2015). In particular, when more than one sensory modality was tested in a single study, we selected only results from the auditory modality (i.e., auditory reaction times), thus concentrating on the effects of mobile phone-like EMFs on the auditory system. This criterion is justified by the rationale that the peri-auricular temporal area is the most exposed to the thermal effects of radiations (see for example Curcio et al., 2004), as also documented

by dosimetric studies (e.g., Cardis et al., 2008). Most of studies on human cognitive performance can be included in three categories, two of which related to the study of attention (focused attention and speed of processing, divided and sustained attention) and a third associated to the study of memory.

Finally, in the respect of methodological standard, to be assessed relevant and included in this review, studies had to mandatorily satisfy some qualitative criteria, such as: blinding of the study (i.e., at least a single-blind procedure); task trials/ conditions randomisation and/or counterbalancing of exposure sessions; detailed exposure characterization (e.g., main frequency and sub-frequencies of the EMFs, signal modulations, power density, SAR estimation).

Studies Dealing with Attention and Speed of Processing in Adults and Adolescents

In a single-blind, counterbalanced, cross-over design, Koivisto et al. (2000) investigated the effects of mobile phone exposure on response times to twelve different tasks. Forty-eight participants were exposed to both GSM and sham signal for 60 minutes, with the two sessions separated by 24 hours. The results indicated a significant reduction (9 ms) of response time in the simple reaction times task.

Although the RF signal and experimental protocol were akin to Koivisto et al.'s study, Haarala et al. (2003 a, b) extended and methodologically improved the previous experiment by using a double blind design, larger sample size, multicentre testing and some additional tasks. Sixty four participants were enrolled (32 in Finland and 32 in Sweden) and then exposed to a GSM and to a sham signal for about 65 minutes. In this case no significant effects were reported on speed measures in the simple reaction time task.

Curcio et al. (2004) investigated the time-course of RF-induced effects on cognitive performance at different tasks. Twenty volunteers

were randomly assigned to one of two groups receiving the exposure before or during the testing session; half of the participants in each group were exposed to a GSM and half to a sham signal for 45 minutes. Results indicated an improvement of response speed in real exposure (decrease of 47 ms in the simple-reaction time task), and a faster performance of participants exposed prior to the test than of those exposed during the test itself (with a gain of 85 ms). This latter result indicates that a minimal exposure time would be required to induce cognitive effects.

A subsequent study was aimed at investigating the effects of MP exposure on cognitive performance in 32 children (Haarala et al., 2005). Tasks were selected for assessing attention, vigilance (simple-, two- and choice- reaction time tasks, vigilance task), and memory (short-term memory task with four memory load conditions) under GSM or sham exposure. No statistically significant differences between conditions were observed on speed outcomes of cognitive functions.

Hamblin et al. (2006) performed an extension of a previous study (Hamblin et al., 2004, see below) trying to overcome some methodological limitations (small sample size, limited endpoints, multiple statistical comparisons). Thus, 120 participants were exposed to a GSM-like signal, in two separate sessions (sham/sham and a sham/active session). Half of the participants received exposure to the left temporal region, and half to the right one. In both sessions they were asked to attend an odd-ball task. Also in this case, no significant differences were reported on reaction times in the simple reaction time task as a consequence of the exposure to mobile phone signal.

In a singular effort to emulate a real-life exposure, Besset et al. (2005) planned a complex and long protocol of exposure. Fifty-five volunteers participated in a double blind study lasting 45 days (3 of baseline, 28 of exposure period, 14 of recovery): during this period they were exposed 2 hours per day, 5 days per week to a EMFs-on or EMFs-off signal. Four cognitive assessments were carried out: at baseline (day 2), during the

exposure period (day 17 and 32) and in the recovery phase (day 45). Despite the study was designed to reveal medium-term size effects, no impact of exposure on psychomotor performance was found.

Keetley et al. (2006) aimed at investigating the effect of exposure to GSM signal on some different cognitive tasks administered to a large sample of 120 volunteers, controlled for age, education, gender. They detected an impairment of performance in a simple reaction time task (digit span) as a consequence of exposure to GSM-like signal.

Similar to other studies which attempted to control for methodological limitations (small sample size, single blind design, type of exposure signal) of previously published studies, Russo et al. (2006) enrolled 168 volunteers to investigate the effect on attention of 35-40 min exposure to a pulsed (GSM-like), CW, and sham signal. The exposure was directed either to the right or to the left temporal region. Despite methodological improvements (double-blind, counterbalancing of conditions, cross-over design), no effect of exposure on measures of attention and speed processing was reported.

Independently by Russo and co-workers, Haarala et al. (2007) conducted a study with very similar set-up and methodology. In this case, 36 volunteers were exposed to three different conditions: pulsed (GSM), CW, and sham signal. Again, exposures were localized on both the left (45 min) and right (45 min) hemispheres. As in the Russo et al.'s study, they reported no effect of exposure to real signal on response times in a simple reaction time task.

In a study by Regel et al. (2007 a) participants were exposed to three different conditions: pulsed GSM, CW, and sham signal. The two RF signals used the same frequency (900 MHz) and specific absorption rate (SAR). The EMFs irradiation lasted for 30 min and was directed over the left ear. Results indicated no significant effect on response speed in a simple-reaction time task. The same group (Regel et al., 2007 b) aimed at investigating possible dose dependent effects of GSM signals on attention and memory tasks. Fif-

teen participants were exposed over their left ear for 30 min. Also in this case, the authors reported no significant difference between conditions in the simple reaction time task.

Curcio et al. (2008) attempted to test the possible cumulative effects of brief (15 min) and repeated (3 times) exposures in a single daily session. Using an exposure setting identical to the previous work (Curcio et al, 2004), 24 volunteers were exposed to both GSM and sham signal: immediately after, they were asked to complete two psychomotor tasks. No statistically significant difference arose as a consequence of exposure to the GSM radiation.

As an extension of Regel's studies, Schmid et al. (2012) exposed 30 participants to two differently modulated GSM signals (14 and 217 Hz, respectively) and to a sham condition: the exposure was carried out before sleep and lasted 30 min. Attention and working memory performance were assessed during the exposure. Results indicated no statistical evidence of an influence of EMFs signals on the attentional performance.

With respect to studies on adolescents, recently Loughran et al. (2013) carried out one of the first studies on young people. In this case the research aimed at investigating the potential sensitivity of teens to mobile phone-like RF EMFs irradiation. Participants underwent three experimental sessions in which they were exposed to mobile phone-like RF EMFs at two different intensities, and to a sham session. Cognitive tasks were performed during the exposure period. The authors reported no effect of exposure on performance in a simple reaction time task.

Studies Dealing with Divided and Sustained Attention in Adults and Adolescents

The large spectra of tasks used by Koivisto et al. (2000) included a subtraction and a vigilance task. They exposed 48 participants to GSM and to sham signal for 60 minutes: the two sessions were separated by 24 hours. Results indicated

a significant reduction of response time in the vigilance task (reduction of 25 ms).

Croft et al. (2002) investigated the influence of mobile phone exposure on neural functioning, including performance in an auditory discrimination task. Twenty-four participants were exposed to 20-minutes GSM or sham exposure. During the exposure, participants completed the discrimination task four times. No significant differences were observed on reaction times.

Lee et al. (2003) tested 78 university students performance in different tasks, including an auditory vigilance test. This task involves withholding pressing a key for targets that occur infrequently. Participants in the experimental group performed better on this test only after they had been exposed to the GSM EMFs, thus suggesting an improvement of attention in the participants.

In a study proposed by Curcio and coworkers (2004), still discussed before, also a choice reaction time task has been administered to participants: in this case shorter reaction times (reduction of 40 ms) have been observed as a function of MP-like exposure.

Interestingly, an examination of medium term effects had also null results. Indeed, as we already discussed, Besset et al. (2005) used both choice reaction time tasks and sustained attention tasks in their battery of daily tests. These tests confirmed the absence of exposure effects on response speed.

As briefly introduced before, Hamblin et al. (2004) studied the effects of mobile phone exposure on psychomotor performance during an auditory task. Here, 12 participants were exposed to a GSM and sham signal for a total duration of 60 minutes. The choice reaction time task required participants to respond to target auditory stimuli by pressing the mouse button as fast as possible. A statistically significant difference in reaction times between real and sham conditions was accounted for by a reduced speed under real exposure (i.e. an increase of 53 ms). However, as no correction for multiple comparisons was applied, any conclusive interpretation of the data is compromised.

As already discussed in the previous paragraph, Keetley et al. (2006) reported mixed results, with an unexpected impairment of choice-reaction times and sustained attention. However, the authors did not apply any correction for multiple comparisons.

As previously described, Russo et al. (2006) and Haarala et al. (2007), assessed the effects of GSM, CW (same frequency as the GSM-signal), and sham signal on a choice-reaction time task. No effects of exposure on measures of speed were found.

Unterlechner et al. (2008) carried out a double-blind crossover study on 40 volunteers, assessing the effects of Low and High UMTS signal compared to Sham exposure on divided attention and vigilance tasks. Also in this case, no significant differences were reported on response speed.

In a study mainly aimed at investigating EEG features during an auditory oddball paradigm, Stefanics et al. (2008) exposed 36 participants to a UMTS and sham signal for 20 minutes. Performance (accuracy index) was tested before and after exposure: also in this case, no statistically significant effects of exposure were reported.

As already anticipated, Schmid et al. (2012) exposed their volunteers to two differently modulated GSM signals (14 and 217 Hz, respectively) and to a sham condition for 30 min before sleep. Again, the attentional task (choice reaction time task) did not vary as a function of exposure to RF EMFs.

With respect to the youngest, Haarala et al. (2005) tested 32 children under both sham and MP-like exposure, using a choice reaction time task (similar to the one used in Curcio et al., 2004) and a vigilance task. No effects due to the irradiation were reported in the two measures. A further experiment on adolescents was carried out by Preece et al. (2005): these authors investigated the effect of EMFs by means of participant's response times: again, no effects were observed.

Studies Dealing with Memory in Adults and Adolescents

Krause et al. (2000) enrolled 16 participants to complete an auditory verbal memory task, under both a 30-min GSM and sham condition, and exposed them over the right posterior temporal region. They reported no significant effect on performance as a function of exposure. Yet, the authors attempted to systematically replicate this study with methodological improvements (Krause et al., 2004). The participants were asked to complete an auditory verbal memory task lasting about 60 min (30 min under real GSM signal and 30 min under sham exposure). Here, at variance with the previous study, the left posterior temporal region was irradiated. Anyhow, no significant effects between conditions were reported.

In addition, as outlined in the previous sections, Koivisto et al. (2000) included a subtraction task. Their results indicated a significant reduction of response time (mean reduction of 29 ms), indicating an improvement of memory performance as a consequence of irradiation.

The multicentre study (two separate laboratories in Finland and Sweden) by Haarala et al. (2004) also investigated the short term memory task with varying memory load (0-, 1-, 2- and 3-back). No significant effect was observed on memory performance as a function of exposure to the GSM signal.

Haarala et al. (2003 b) within a study on the effects of a GSM exposure on cerebral blood flow, assessed the working memory of their participants. The task was similar to the one used in previous studies by the same group (Krause et al., 2000). Behavioural data were recorded on 10 participants, each exposed to both GSM and sham signal for about 45 minutes. No significant effects were reported on memory functioning. Some years later, the same research group carried out a new study on the effects of mobile phone exposure on cerebral blood flow (Aalto et al., 2006). Behavioural data were obtained by a simple working memory task (1-back task) in 12 participants during a 51 min

exposure to a modified GSM and sham signal. As in the previous study, no effects on memory performance were observed.

Curcio et al. (2004) reported a significant effect in a subtraction task, with shorter reaction times (i.e. reduction of 40 ms under real with respect to sham exposure). However, the same type of task applied to a much larger sample size ($n=168$) revealed no significant effect on reaction times (Russo et al., 2006).

Besset et al. (2005) investigated memory according to several tasks. A verbal learning task required to recall the maximum number of words remembered of a 15 words list. A sixth delayed recall was performed 45 min after the fifth presentation. The working memory was assessed with the digit span backward, the spatial span backward, and the number letter sequencing. In the backward task the participant was asked to repeat the sequences in exactly reversed order. In the number letter sequencing task the participants were required to listen to an auditory presentation of alternating numbers and letters and to repeat them back. No effect of mobile phone exposure on the reaction time performance in these tasks was found.

Krause et al. (2007) aimed to assess the effects of continuous wave (CW) and pulse modulated EMFs on brain functioning, and the possible presence of differences between left and right side EMFs exposure. These authors carried out two different experiments, each one on a sample of 36 healthy males: one with the auditory verbal memory task and one with the visual sequential letter memory task. Each experiment included six exposure conditions: sham, continuous wave, and pulse modulated wave were irradiated on both left- and right-side of the head. No significant effects were reported on speed of memory performance.

In one of the previously discussed studies by Regel et al. (2007 a), also auditory working memory was investigated. The results indicated a significant increase of response speed in the 2-back and 3-back tasks during real exposure. These effects appeared to be greater during the pulsed

condition than during the CW and sham conditions. No significant differences were observed when applying the simplest (1-back) condition for working memory. As the authors stated, these results show a significant improvement in memory performance, albeit subtle. In the following study proposed by the same group (Regel et al., 2007 b) previous results were not confirmed, since an isolated trend to increase of speed in the 1-back task as a function of the increase of field intensity was reported.

Sauter et al. (2011) aimed to compare possible cognitive effects of GSM and WCDMA/3G UMTS signals. In this study a 9 days long duration (7h 15 min per day) exposure was directed to the head. Of the 9 days, 3 were dedicated to GSM, 3 to WCDMA/3G UMTS, and 3 to sham conditions; consecutive experimental days were separated by two weeks. A 0- and 2-back task was administered twice every experimental day during the exposure. No statistically relevant effect of exposure was reported.

Schmid et al. (2012), in their study assessing the effects of two differently modulated GSM signals (14 and 217 Hz, respectively) with respect to sham condition, reported a reduction in speed performance at 2-back task under 217 Hz pulse-modulated exposure.

Finally, Leung et al. (2011) were the first to investigate the differential effects of RF emitted by mobile phones of second (2G, namely GSM) and third generation (3G, namely UMTS) on three groups of volunteers: adolescents, young adults and elderly. Each participant was exposed to three exposure conditions (sham, 2G, 3G) during which an n-back task at varying cognitive load (1-, 2-, 3-back) was administered. No effects on response speed were observed.

FUTURE RESEARCH DIRECTIONS

Most of the research findings here reported were included in two meta-analyses. Valentini et al. (2010) reviewed papers published in the period

1999-2008. Of the 42 relevant studies, 24 met the inclusion criteria (presence of real and sham condition in human provocation/laboratory studies; at least single blinded experimental studies; acute exposure to GSM and UMTS signals; enrolment of healthy subjects; inclusion of cognitive tests used at least once in other studies and reporting speed measures; randomization and/or counterbalancing of exposure sessions/conditions; detailed exposure characterization; unbiased statistical analyses). Results overall point to a lack of short-term acute effects of GSM-EMFs exposure on reaction times. Yet, most of the poorly methodologically-statistically controlled studies reported a faster performance in the simple reaction time task (measure of attention), 2-back task and 3-back task (measures of working memory) following GSM-RF exposure. Such effects disappeared when effect size was controlled for, by excluding outlier papers characterized by highest heterogeneity. Moreover, some of these positive findings were reported by studies with methodological flaws, as for example studies providing only single blind procedure. In fact, the replication of the same study with a double blind procedure systematically brought about negative findings. Summarizing, based on Valentini et al. (2010) results, it can be concluded that GSM-EMFs exposure does not produce relevant and consistent effects at cognitive level.

Most recently, Barth et al. (2012) came to the same conclusions. The authors searched for papers published until February 2011: 29 papers were reported and 17 of them fulfilled the requirements and were included in the analysis. Despite less stringent inclusion criteria were applied, results indicated no consistent short-term effects of GSM on the 11 cognitive outcomes taken into consideration (speed of processing, focused and sustained attention, working memory). To date, some of these studies initially reporting an effect of mobile phone-like EMFs exposure were subsequently replicated with statistical and methodological improvements: in all these cases positive findings were not confirmed. It should be stressed

that also some of the studies reporting no effects of exposure suffered from weaknesses, e.g. few participants, fixed order of exposure conditions, tasks administered in fixed sequence. Yet, there is thus no reliable and consistent evidence that cognitive performance of healthy adults is influenced by RF exposures. Too few studies on cognition have been conducted with children and adolescents to allow a final conclusion for this group.

Since the available literature, future research should be focused on the medium- and long-term effects to repeated EMFs exposure. So far, no psychomotor and cognitive effect has been found with daily acute repeated exposures (three 15 min exposures each day; Curcio et al., 2008), or in medium-term exposure designs (more than 7 h per day, for non-consecutive 9 days; Sauter et al., 2011; 2 h daily exposure over 3 weeks; Besset et al., 2005). The existence of possible middle- and long-term effects of mobile phone-RF exposure remains unresolved and is a cause of concern, especially regarding people in a developmental period. At present, in fact, only three reliable peer reviewed studies have been published on children and teenagers, and in all no significant effects on memory or attention performance were reported (Haarala et al., 2005; Preece et al., 2005; Loughran et al., 2013). Thus, more research is needed on potentially sensitive populations (children, the elderly, neurological impaired patients, RF workers, etc.) and caution should be urged until robust findings will motivate the exclusion of any potential risk (WHO, International Project Research Agenda, 2010). All these observations and suggestions should also be taken into consideration by international organizations as WHO when developing the ongoing Environmental Health Criteria (EHC) for RF-EMFs.

CONCLUSION

The first studies on humans addressing cognitive functioning changes as a consequence of radiofrequency (RF) EMFs exposure, date back

to almost 20 years ago. The effects on human behaviour showed in those pioneering works indicated a somewhat improvement of performance under the exposure to the signal, compared with sham exposure. These first and striking results were not fully replicated by subsequent studies that were characterized by a more methodological robustness and attention to exposure aspects. In accordance with this view, latest reviews and metaanalyses have confirmed the paucity of evidence and the lack of reliability of psychomotor and cognitive effects of acute RF EMF exposure on human volunteers, particularly when assessed in well controlled laboratory settings. Thus, despite the public opinion about potential biologic effects of acute RF EMFs irradiation, it can be concluded that to date there is substantial lack of evidence about a negative influence of non-ionizing radiations on cognitive functioning in humans.

ACKNOWLEDGMENT

I wish to thank Elia Valentini (now at the Department of Psychology, University of Essex) a friend and colleague with which I worked for some years on this topic and that co-authored some previous critical reviews that are the basic and logical ground for the present contribution.

KEY TERMS AND DEFINITIONS

Attention: The process of directing psychomotor and cognitive resources on a task.

Auditory Effects: The result of the irradiation exposure on the auditory function.

Behavioral Effects: The result of the irradiation exposure on the motor responses.

Cognitive Effects: The result of the irradiation exposure on, more generally, any cognitive activity measured by laboratory tasks.

EMFs: Electromagnetic fields are physical fields produced by electrically charged objects. The magnetic counterpart of the field is determined by the movement of the charged object.

GSM: Global System for Mobile communication. It was one of the most widely used wireless telephony technologies before the advent of 3G protocols.

Memory: The process of storing and retrieving or recognizing information.

Radiofrequency: Electromagnetic fields have frequencies of radiation in time and space. These go from large wavelength and slow cycles such as 3 KHz to short wavelength and fast cycles such as 300 GHz.

Reaction Time: The time lapsing between a stimulus and a response.

Identification of Wireless Devices From Their Physical Layer Radio-Frequency Fingerprints

INTRODUCTION

Extensive research has been performed in recent years for the identification of wireless devices from their radio frequency (RF) emissions both intentional or unintentional. The term “intentional” is used to identify the RF emissions generated by a wireless device to implement a specific wireless standard. For example, the RF emission of the uplink transmission of a mobile phone, which implements a specific wireless communication standard. The term “unintentional” instead, identifies the RF emissions not directly related to the services offered by the wireless device or the wireless standard, but which are generated due to the operation of the device. For example, the RF emission generated by the electronic components of the device. It is well known in literature that electronic devices can release RF emissions containing information on the operation of the device, thus disclosing sensitive information and generating a security threat. This was one of the primary drivers for the definition of the TEMPEST (Telecommunication and Electronic Material Protected from Emanating Spurious Transmission) standard. TEMPEST refers to the possibility of spying on information systems through leaking emanations, including unintentional radio or electrical signals, sounds, and vibrations (see Rohatgi,

P., (2009) for a description of the TEMPEST standard). This issue is also known as emission security (EMSEC), which is a subset of communications security (COMSEC). Since there is already a well-defined standard (i.e., TEMPEST) and a considerable amount of work in EMSEC and COMSEC for “unintentional” emissions, this chapter focuses only on the collection of fingerprints from “intentional” emissions, which are generated by the wireless device while performing its communication function or other services.

The main idea of identifying a wireless device through its RF emissions is that the electronic circuits and the RF components have specific characteristics determined by the production and manufacturing processes. These characteristics, which result in unique differences, can be used to distinguish a wireless device from another. The RF components can include filters, amplifiers, oscillators and other electronics, which are used to compose and transmit the RF signal. The differences on the electronic components are randomly generated, and are mainly due to imperfections in the material or the component itself. For example, the material can have impurities due to the presence of different substances or tiny differences in the soldering or casing of the amplifier, which have an impact in the generation of the RF emissions. These imperfections

appear as a subtle modification of the RF signal in space even if the wireless device generates a signal conformant to the standard. For example, a GSM mobile phone can transmit a RF signal with the modulation and range of frequencies defined in the GSM standard, but the physical imperfections will produce minor changes in the amplitude or phase of the signal, which can be collected and processed by a receiver. Note that these minor changes will be substantially the same from statistical point of view in every transmission of the signal and they can be used as a fingerprint of the wireless component (and, consequently, of the GSM mobile phone). As it will be described in the following sections of this article, machine learning or signal processing techniques can be applied to the collected RF signal to extract the imperfections and the related fingerprints.

RF fingerprints can have many applications if the level of identification accuracy is high (e.g., 80-90% or more). The possibility of identifying wireless devices from their RF fingerprints can be used for multi-factor authentication, where a wireless device can be authenticated not only on the basis of conventional cryptographic methods but also by processing the RF fingerprints. Another potential application is to fight against the distribution of counterfeit products. Counterfeit wireless devices (e.g., mobile phones) have electronic components of worst quality in comparison to the genuine ones (Tehranipour et al., 2015). For example, if a counterfeit phone has been built with low grade RF amplifiers in the uplink transmission chain, it will generate different RF fingerprints compared to an original one.

The structure of this article is the following: the *Background* section provides the main definitions and a literature review on this topic. The section *RF fingerprinting methodology* describes the main workflow for the collection and processing of the RF signals to generate the fingerprints. It also highlights the main outstanding challenges. The section *Solutions and recommendations* identifies and describes the potential approach

and techniques that can be used to address the outstanding challenges described in the previous section. In case gaps are identified, the section *Future research directions* describes future possible research developments. Finally, the *Conclusions* section concludes the chapter.

BACKGROUND

The possibility to identify wireless devices from the intrinsic characteristic of their components has grown in importance in the last 10-15 years, due to the improvement in the radio frequency sensors and receivers' capabilities for A/D processing, which have also led to a decrease in price. In fact, the possibility to extract valuable RF fingerprints is possible only when the collected RF signals (i.e., the observables) are digitized with a high degree of clock precision. Many papers describe the use of high-end spectrum analyzers or oscilloscopes to collect and process the RF signal. For example, in Reising et al., (2010), the authors have used a high grade spectrum analyzer to capture and process the signals from a GSM mobile phone. Then the signals were down-converted, digitized and stored as complex in-phase and quadrature (I-Q) components. From the IQ samples, the authors have extracted statistical features, which are representative of the imperfections in the communication path and are used to generate the needed fingerprints. A filter was used to remove bias and unwanted interference, since the latter could degrade or remove the fingerprints. In other words, the collection and processing algorithm would not be able to identify and distinguish the fingerprints in the signal, if the wireless interference had overpowered the fingerprints in the signal. Another important aspect is the need to remove the content related information from the signal, otherwise the fingerprints would be biased by information content. Using this approach only the non-content sections of the GSM bursts are useful for device identification. Figure 1 provides

a description of a GSM burst, where the content related parts are the payload in sections 2a and 2b, while the sections 1,3,4 are non-content related.

On the basis of the previous discussion on the content-related sections, it is clear that the processing of fingerprints mainly depends on the wireless standard or technologies implemented by the RF device. Not only each wireless standard has its own content and non-content parts but different parts of the signal could be more or less suitable for the extraction of the fingerprints. This approach, although standard-dependent, is quite general in scope as most communication systems with the noticeable exception of CDMA have repeatable information patterns such as the Wi-Fi preamble.

In both previous cases, the authors have used high-end receiver systems with a high resolution and A/D dynamic range. Other papers have used also high-end receivers like expensive spectrum analyzers and oscilloscopes as in Bihl et al., (2015) for ZigBee and Reising et al., (2012) for WiMax standard. The advantage of using high-end receivers is that the sampling rate and the dynamic range allow a very high level of granularity to retrieve and identify the fingerprints of the wireless devices. At the same time, the cost of this high-end receiver equipment is in the order of magnitude of thousands of dollars, which does not make practical the collection and processing of radio frequency fingerprinting for a variety of applications like multi-factor security, fight against counterfeiting and so on. To address this issue, some authors have recently investigated the feasibility of fingerprinting with relatively low-cost receivers. An analysis of the impact on the identification accuracy between low-end and high-end receivers was recently reported in Patel et al., (2014), where six different ZigBee devices of the same brand were analyzed using a high cost receiver (i.e., NI PXIe-108) and a low cost software defined radio (i.e., the USRP 2921 model). The cost ratio between the most expensive receiver and the low cost receiver is at least four. The results show a difference of accuracy approximately between 6% and 8% (details are

in Patel et al., (2014)) especially where Gaussian noise is present. Similar results were achieved by Rehman et al., (2012) with the 802.11a standard, where the high-end equipment is a PSA Agilent E4448A spectrum analyzer and the low-end are USRP receivers. We note that the cost ratio for the equipment used in Rehman et al., (2012) (i.e., at least a factor of 10) is even higher than in Patel et al., (2014). The differences in accuracy are also higher: between 10% and 20% even in presence of limited Gaussian noise. The conclusion drawn by these preliminary studies is that the receivers can significantly impact the identification and verification accuracy.

The extraction of the fingerprints is usually implemented by a) extracting statistical features from the signal in space or by b) correlation of the signals as described in Rehman et al., (2014), Danev et al., (2012) and Khanna (2015). The first category has been used by Reising et al., (2010), Reising et al., (2015) and others, where the used statistical features are variance, skewness and kurtosis either in time or frequency. The mutual signal correlation has been used in Sanchez et al., (2015) for DECT device identification. Other techniques like the Hilbert-Huang transform (HHT) can be used to generate various statistical features both in time and frequency, as shown in Zhang et al., (2016) for GSM device identification.

Some of the issues and challenges described in this paper have been identified also in recent surveys on the topic of RF device identification like, for example, in Khanna, (2015) and Xu et al., (2016).

RF FINGERPRINTING METHODOLOGY

Description of the Methodology

As described in several papers, the extraction of fingerprints of wireless devices can be based on the use of different set of features or the different communication standards. However, both

Figure 1. GSM burst with the content and non-content sections, which can be used for fingerprinting
Source: By the authors of this paper.

approaches have a common main methodology. Figure 2 depicts the workflow of the fingerprinting methodology, where the part in blue is common to all the fingerprint generation schemes, while the green and the orange flows represent the branches for the correlation-based and feature-based techniques respectively.

Each step is described as follows:

1. A wireless device (e.g., mobile phone) generates a radio frequency signal.
2. The signal in space is collected by a RF receiver/sensor (the terms receiver and sensor are used in literature with the same meaning). The RF receiver/sensor can be a high-end expensive spectrum analyzer or a low cost digitizer. This phase is critical to support the accuracy for identification and validation because the quality of the collected samples is usually proportional to the identification accuracy. The trade-off is between the cost of the RF receiver/sensor and its components and the level of accuracy. The RF receiver/sensor must provide the following functions described in the figure:
 - a) RF collection or capture of the RF signal in space through an antenna, an amplifier and other components, b) a down sampler to bring down the signal from the operational frequency to the baseband, and c) a digitizer like an A/D converter, which converts the analogic signal in digital samples.
3. A digital filter is usually applied to eliminate RF interference, which could have been captured together with the wanted RF signal.
4. The samples must be averaged and normalized to ensure that the application of the statistical features are coherent, otherwise the fingerprints would be biased.
5. In a similar way, the samples must be synchronized to ensure that the application of correlation or statistical features algorithms is executed on all the signal components at the same time. This step is general in scope and needs to be applied to the radio frequency signals that are composed by bursts such as WiFi, GSM, Bluetooth, etc. The bias introduced by lack of burst synchronization must be removed before the statistical features are applied.

6. At this point, two different techniques are applied (even if combined approaches are also possible). A first set of techniques (the green flow in Figure 2) is based on the application of correlation algorithms. For example, the GSM bursts of different GSM mobile phones are correlated to identify the bursts with higher similarity, which should be linked to a specific mobile phone. Another set of techniques (the orange flow in Figure 2) is based on the extraction of statistical features. For example, the value of variance, skewness or kurtosis are extracted from the GSM bursts to generate a collection of data sets, which can be used as fingerprints. The flows are described in the following steps respectively as flow A) and flow B).
7. (Flow A). The digital samples are correlated among them to evaluate their similarity on the basis of the consideration that digital samples of the same wireless device should be more correlated than the digital samples of different wireless devices. Various correlation algorithms can be used, including Pearson, Kendall or Spearman (see Hollander et al., (2013) for a description of the algorithms). Fingerprints are generated from the results of the correlation.
8. (Flow B). Statistical features are extracted from the digital samples to generate the fingerprints. Various statistical features can be used: from various moments of different orders like variance, kurtosis and skewness to the coefficients of the decomposition of the digital samples in different spectra or transformation (e.g., wavelets). The assumption demonstrated in literature is that the specific characteristics of the wireless devices can be captured to a different degree by the statistical features. The challenge is to identify the most appropriate or most representative features.
9. (Flow B). The statistical features extracted from the digital samples are processed through machine learning algorithms that can be both based on supervised or unsu-

pervised learning. In supervised learning, a training phase is performed. Then, the observables from a wireless device to be identified or validated are compared against the training set.

Removing Bias: Issues and Challenges

An important issue, which was highlighted by recent studies (Rehman et al., 2012), (Patel et al., 2014) and (Wang et al., 2016) is the influence of the receivers on the collection of the physical layer fingerprints and the issue of portability. When the signal is collected by the receiver, the digital samples do also contain the fingerprint of the receiver or they are biased by the specific limitations of the receiver. This phenomenon is more relevant in low quality and cost effective receivers because they introduce more bias. In particular, there is a strong difference between the fingerprints of high-end and low-end receivers as highlighted in Wang et al., (2016) and Patel et al., (2014). Even within receivers of the same class, the portability issue appears. As shown in Rehman et al., (2012), the fingerprints collected by one receiver cannot be directly used by another receiver for identification. In other words, if a receiver captures the observables and the tester uses this observable against a set of fingerprints generated with another receiver of the same class but different model, the identification process will usually fail. In Rehman et al., (2012), the authors have proven this aspect with a low cost USRP software defined radio. The identification accuracy will not be adequate in order to recognize the same wireless device on the basis of the fingerprints taken by the different receivers. This research problem still has to be solved. An example of this phenomenon can be seen in Figure 3, where the statistical features of Variance and Skewness are extracted from the RF observables of a single nRF51822 SoC RF module by using two different RF SDR USRP receivers (in green

and black). However, we can see clearly that the fingerprints are quite different among the different receivers even if the signals have been averaged and normalized.

Another relevant issue is that RF fingerprints may not be always collected in ideal conditions of Line of Sight (LOS) and absence of RF noise. While a reference library of RF fingerprints could be generated in ideal conditions, the RF observables for identification or validation could be impacted by the presence of attenuation and fading. Various authors have investigated the impact of Gaussian Noise (Reising et al., 2015) or Fading (Wang et al., 2016) and the result is obviously that accuracy will get worst in a proportional way to the presence of Gaussian Noise or Fading effects. An example of the impact of the attenuation on the identification accuracy is shown in Figure 4 for the identification of mobile phones supporting the GSM standard, where the X axis shows the Signal to Noise Ratio (SNR) expressed in dB, while on the Y axis it is reported the identification accuracy. The identification accuracy is calculated as the ratio of the sum of True Positive (TP) and True Negative (TN) over the total number of samples: $TP+TN/(TP+TN+FP+FN)$ where FP are the False Positives and FN are the False Negatives. The picture represents the identification of the accuracy between an Apple, a HTC, a Sony and a Samsung mobile phone, all supporting the GSM standard. The accuracy has been calculated using a Support Vector Machine (SVM) supervised learning algorithm.

Finally, either the wireless device or the receiver could be impacted by environmental conditions or lack of synchronization. While the clock drift of the wireless device could be itself an element to generate a physical fingerprint of the device, lack of synchronization in the receiver could affect the identification accuracy or the collection of the observables from the wireless device to build the fingerprints. Temperature could also influence the collection and generation of fingerprints even if there is a scarcity of studies on this aspect.

SOLUTIONS AND RECOMMENDATIONS

In this section, we describe the potential solutions to address the issues described in the previous section. The issue of the bias introduced by the receiver in the collection and generation of the fingerprints of a wireless device could be theoretically mitigated in two ways:

1. By calibrating the receiver to remove the bias in the collection phase.
2. By identifying the receiver bias, recording it and applying it in the processing phase of the wireless device observables to remove it, so that the generation of the fingerprint is neutral against the receiver model.

This approach is not new and it is indeed applied in radio frequency measurements to remove the bias of the test equipment in measurement campaigns so that the test results are independent as much as possible from the bias of the test equipment and they are reproducible. Ideally, a reference signal, which is representative of the wireless communication standard supported by the wireless device, could be used to evaluate the bias of the receiver. The reference signal could be generated by a signal generator or similar test equipment. If such equipment is not available, a wireless device could be selected as a golden reference to evaluate the bias of the receivers. We note that this approach has not been studied in detail in literature even if it was only recently recommended by Wang et al., (2016).

The issue of non-ideal conditions for the collection of the fingerprints from wireless devices could be addressed by defining models for the attenuation and fading effects and applying them to the extraction of the fingerprints. The models must still be calibrated to the context where the observables are collected. In other words, the environment where the signal is collected should be evaluated and calibrated to identify which attenuation or fading model applies and what

are the parameters defining the model. This task may not be easy to achieve and it is obviously highly dependent on the context where the radio frequency measurements are taken. In another environment, the same models and parameters may not apply. An alternative approach is to select statistical features or correlation algorithms more resistant to attenuation and multi-path fading effects. A number of papers ((Reising et al., 2010), (Danev et al., 2012), (Wang et al., 2016), (Patel et al., 2015)), have investigated the impact of attenuation and multi-path fading on the identification accuracy. In particular, (Wang et al. 2016) have defined attenuation and fading models for fingerprinting and tested them against a specific wireless standard. In a similar way, the authors in Patel et al., (2015) have investigated the impact of attenuation (i.e., decreasing values of Signal to Noise Ratio) on the ZigBee wireless standard for different set of features and different algorithms.

Lack of synchronization or presence of clock drift in the receivers can be mitigated by synchronizing the receivers with Global Navigation Satellite Systems (GNSS) or by re-synchronization of the digital samples in a post processing phase. This latter approach may not be used when the fingerprint is the clock drift itself as described in Lanze et al., (2012) and Polak et al., (2015), then it is recommended to use the former approach whenever possible (e.g., when GNSS receivers and signal is available).

Finally, the dependency on the environment has still to be investigated by the research community. Even if many wireless devices are designed and built to provide stable performance in a wide range of temperatures (for the obvious reasons that they should support wireless communication in different context), there are limited studies about the performance of identification based on RF fingerprinting as pointed out in Rehman et al., (2014). The authors in Tekbas et al., (2004) have observed that a change in environmental conditions such as battery voltage or ambient temperature causes the statistical features vectors to spread over the feature space, resulting in classification

performance degradation. In the same reference (Tekbas 2004), it was experimentally shown that performance degradation resulting from changing environmental conditions can be compensated for by training the system with data collected in a range of battery-voltage and ambient temperature levels.

FUTURE RESEARCH DIRECTIONS

The future research directions are linked to the issues and solutions identified in the previous sections. New statistical features, which are resilient to multi-path fading effects, could be investigated to improve the identification accuracy in difficult propagation conditions. Here, the extensive work already done in the definition of signal processing algorithms to overcome multi-path fading in wireless communication or radar systems could be applied to fingerprinting. New statistical features could focus on the components of the radio frequency signal, which are less impacted by the multi-path fading effects.

The issue of portability of the fingerprints from one receiver to another remains a very important challenge to overcome if RF fingerprinting has to become a practical mean for identification or multi-factor authentication (Rehman et al., 2012), (Patel et al., 2014). In this context, researchers may investigate the most effective way to remove the fingerprints or bias of the receivers either by calibrating them or by comparing a set of RF fingerprints from golden references. Most of the work done so far in RF fingerprinting has been experimental: researchers have collected RF signals from wireless devices and processed them with algorithms and with a selection of different statistical features. The selection of the best algorithms or statistical features are mostly based on the experimental results. Future research directions should focus on the definition of theoretical models to identify the elements, which may increase identification accuracy and portability of the fingerprints. Since fingerprints are based on

subtle differences in the electronic components and materials, a joint effort between researchers in wireless propagation, machine learning and electronic materials could be beneficial.

CONCLUSION

This chapter describes the main techniques for the fingerprinting of wireless devices using their RF transmission. The focus is only on the collection of fingerprints from “intentional” emissions because there is already a consolidated literature for “unintentional” ones. Several articles have shown that for commercial systems such as WiFi, GSM, Bluetooth, and others, fingerprinting in ideal conditions can achieve high identification accuracy (e.g., 80-90% or more). This can be used for multi-factor authentication, where a wireless device can be authenticated not only on the basis of conventional cryptographic methods but also by processing the RF fingerprints. Another potential application is to fight against the distribution of counterfeit products. To support these applications, there are still some key challenges to overcome. This chapter tries to identify them in this context as well as providing possible approaches to solve them. Further research work is needed to investigate the portability issues between fingerprints taken using different receivers, as well as to identify and remove potential other sources of bias.

KEY TERMS AND DEFINITIONS

Fingerprint: A specific characteristic of a wireless device.

Reference Library: Library of fingerprints of wireless devices.

RF Emissions: Emissions of wireless device in the radio frequency spectrum.

Software Defined Radio: A radio communication system or receiver where the functions to process the radio frequency signal are implemented in software rather than hardware.

Statistical Features: Features of a data set, which can be defined and calculated through statistical analysis.

Supervised Learning: The machine learning task of deducing a function from a set of labeled training data.

Unsupervised Learning: The machine learning task of deducing a function to describe hidden structure from a set of unlabeled data.

Wireless Device: An electronic device capable of transmitting and receiving information using radio frequency spectrum.

The Impact of Mobile Phones on Plastic Surgery and Burn Management

INTRODUCTION

Traditionally defined as “a specialized branch of surgery concerned with deformities and defects of the integument (the skin) and the underlying musculoskeletal framework” (Converse, 1997, p.3), plastic surgery nowadays combines traditional areas of expertise and principles with innovation; the plastic surgeon performs operations in diverse anatomical areas of the body, using creativity and innovation to restore the form and function affected by traumatic injuries, burns, congenital abnormalities, and losses caused by infection, tumours or cancer excision (Thorne, 2007). Subdisciplines of plastic surgery may include, amongst others: cosmetic or aesthetic surgery, burn surgery, craniofacial surgery, hand surgery, microsurgery and paediatric plastic surgery.

Although recognized as a specialty with extensive field of work, plastic surgeons are not always available in most hospitals around the world; besides, plastic surgeons are usually busy seeing patients in their offices, running between different hospitals and clinics, or operating, which makes them difficult to reach by emergency department doctors and in training young surgeons. There is an even greater shortage in developing countries, particularly in rural areas where, due to costs, distances to bigger centres must be considered

before the referral of patients who need assessment from the specialists. To address this issue and improve patient care through cost saving and time efficiency, an exponential growth for *telemedicine* (from the Greek prefix *tele* meaning ‘at a distance’ and the Latin word *meden* meaning ‘healing’) services in the field have been identified in recent years, varying from consultations by the telephone and image transfers with the purpose of diagnosis at a distance, to the complex technology of telesurgery (Grunwald, Krummel, & Sherman, 2014).

The new generation of smartphones are mobile phones with more advanced computing capability and connectivity. They boast higher resolution built-in digital cameras; larger crystal display screen; capacity to store data and images in archives; access to wireless data allowing online communication anywhere in the world and access to mobile applications – apps (Smartphone, 2014). These smartphones are equipped with the necessary technology to fulfil the prerequisites for a complete telemedicine system (‘m-health’), which by the World Health Organisation’s definition includes:

... the delivery of health care services, where distance is a critical factor, by all health care professionals using information and communica-

tion technologies for the exchange of valid information for diagnosis, treatment and prevention of disease and injuries, research and evaluation, and for the continuing education of health care providers, all in the interests of advancing the health of individuals and their communities. (World Health Organisation [WHO], 1998, as cited in WHO, 2010)

In the field of plastic surgery, patient's conditions are basically evaluated by visual inspection (including acute traumatic wounds and burns), and mobile phones may be used in remote, rural and resource-poor settings to provide essential information to specialists in larger and academic centres. Plastic surgeons are able to assess images and data and define management strategies required for those patients. Communication occurs not only between the plastic surgeon and the referring physician from other sites in the emergency setting, but also between plastic surgeons and patients (for continuity of care); nurses and plastic surgeons (for surgical care instructions); junior/trainee and supervisor/mentor plastic surgeons (for management instructions), and between senior plastic surgeons and their peers (for remote collaboration on diagnostically complex cases).

The availability of information in mobile technology has also allowed a growing market for education tools for plastic surgeons and their potential patients, and the use of social media for marketing's purpose.

In this chapter, the authors review the available literature on the use of mobile phones in the field of Plastic Surgery and Burns.

BACKGROUND

The majority of published studies debate telemedicine in plastic surgery using one of the two conventional systems, either the *store-and-forward (pre-recorded, asynchronous)* mode, which involves prior storage of still images or videos followed by transmission of the data (Buntic et al.,

1997; Roa, Gomes-Cia, Acha & Serrano, 1999; Baldwin & Langton, 2001; Pap, Lach & Upton, 2002; Jones, Milroy & Pickford, 2004; Wallace, Smith & Pickford, 2007; Varkey, Tan, Girotto, Tang, Liu & Chen, 2008; Wallace, Jones, Milroy & Pickford, 2008; Diver, Lewis & Gordon, 2009; Gray, Armfield & Smith, 2010; Trovato, Scholer, Vallejo, Buncke & Granick, 2011; Hoppe, Lee, Granick, & Scott, 2014) or the *real time (video conferencing, synchronous)* mode, which implies the interaction between patient, referring physician and specialist at the same time (Syed-Abdul, Scholl, Chen, Santos, Jian, Liou & Li, 2012).

Studies using mobile or cellular telemedicine, where portable devices with in-built camera capture digital images and computing and networking features allow direct and real time interaction, are still scarce but have shown promising results, particularly related to low costs associated with the use of this technology. Lam, Preketes, and Gates (2004), at Nepean Hospital in Australia; Tsai, Pong, Liang, Lin and Hsieh (2004) and Hsieh, Tsai, Yin, Chen, Yang and Jeng (2005), at Chang Gung Memorial Hospital in Taiwan; Saffle (2006), from the University of Utah, USA, and Shokrollahi, Sayed, Dickson, and Potokar (2007), from United Kingdom were amongst the earliest to report the successful use of mobile phones for teleconsultation in plastic surgery and burns.

Probably due to ethical and medico-legal issues related to the use of images and security concerns, and due to limitations to perform proper randomised controlled studies on the use of telemedicine, only a few more studies have been further published on the application of m-health for plastic surgery-related topics (Knobloch, Gohritz & Vogt, 2009; Knobloch, Rennekampff & Vogt, 2009; Engel, Huang, Tsao, Lin, Chou & Brey, 2011; Farber, Haik, Liran, Weissman and Winkler, 2011; Suliman, 2013; Hernandez, 2016. Wani, Rabah, AlFadil, Dewanjee & Najmi, 2013). Gardiner and Hartzell (2012), from Addenbrooke's Hospital in Cambridge, United Kingdom; and Wallace, Hussain, Khan and Wilson (2012), from Queen Elizabeth Hospital, Birmingham, United

Kingdom; Atiyeh, Dibo, and Janom (2014) from the University of Beirut, Lebanon performed a literature review of studies published on telemedicine for plastic surgery and burns, discussing technical and legal issues associated with this technology, including with the use of mobile phones.

More recently, plastic surgeons have been exploring the use of mobile technology for online education (m-Learning), research, and marketing. Recent publications have begun to explore smartphone applications more pertinent to plastic surgery (Amin, 2011; Amin, Edmonds, Abboudi & Sivakumar, 2012; Freshwater, 2011; Molajo, Vaiude & Benson, 2011; Workman & Gupta, 2013; Al-Hadithy & Ghosh, 2013; Valente, 2015

Australia, where Lam, (Lam, Preketes & Gates, 2004), who was undergoing training in Plastic and Reconstructive Surgery, used mobile phone photo-messaging for 27 cases of hand trauma (fractures, wounds, loss of fingertips, burns and infections) for correspondence between him and the consultant in the emergency department over a two-month period. He discussed the management with his senior consultant and sent the pictures, changing his strategy in four cases after checking out with his seniors. In this study, he recommended the use of mobile phone photo messaging into the clinical practice, stressing the low cost and ease of use of the available technology.

The same methodology was used by Tsai and colleagues (2004) at the Chang Gung Memorial Hospital, in Taiwan. A total of 60 patients and 82 extremity wounds were analysed for teleconsultation using transmission of 182 images through the remote camera phone. Despite the small dimension of the display screen, the quality of images was sufficient for identification of selected wound descriptors (gangrene, necrosis, erythema, and cellulitis) in the majority of the wounds, comparing the onsite evaluation with the remote assessment. The authors added as limitation of the study the restricted use of mobile telephone in some hospitals; the skills of the onsite photographer and intensity of circumstantial light in image acquisition interfering with quality of image acquired and further interpretation; and the need for a proper complete examination and transfer of information from the onsite examiner to the remote clinician for an adequate diagnostic and recommendation for management.

Hsiek and colleagues (2004) reviewed 45 mobile phone images of soft tissue injury of 81 digits, founding 76% sensitivity and 75% specificity for the remote diagnosis of the skin defect. In 25% of the cases reviewed, there was some discordance of opinions amongst the researchers involved which was explained by the low-resolution digital image and difficulties in the on-site physical examination, but the authors recommended the use of the mobile camera-phone associated with

CURRENT SCIENTIFIC KNOWLEDGE ON THE USE OF MOBILE PHONES IN PLASTIC SURGERY AND BURNS

1. Mobile Phones used for Teleconsultation in Acute Emergency Plastic Surgery

Plastic surgeons have always relied on photographs of their patients for comparison of pre and post operative results, for presentation in scientific meetings, or publication in peer-reviewed journals with educational purpose and dissemination of information within the scientific community. The technological upgrade from the former analogical cameras to the current digital cameras has resulted in better image resolution associated with better system for storage and filing of the images obtained. The advent of smartphones has lead to an even simpler and relatively less costly way to perform the same task, resulting in the substitution of the outdated and costly digital cameras for the practicality of the high-resolution, built-in camera-phones associated with all the technological package brought in with the most recent smartphones.

One of the former publications in this field is the study at Sydney's Nepean Hospital in

on-line verbal communication and review of the transmitted captured image by a senior specialist. They stressed the ease of use, low cost, high portability and mobility of this system, and the potential for future applications in telemedicine and telecare.

Farber and colleagues (2011), from the Sheba Medical Centre in Israel, used more advanced mobile phone technology to assess 57 patients; 58 multimedia consultation were performed between junior and senior plastic surgeons, using digital photograph from integrated phone camera sent via MMS (multimedia messages), video calls or video clips. The study suggested that high resolution images provided by this technology create an objective language that is not limited by the verbal skills of the examiner (junior doctor under training) nor by the listening comprehension of the senior doctor (specialist consultant). The transmission of videos was also an advantage, as there was no need for a specialized videoconferencing setting.

At the University of Heidelberg, Germany, Engel and colleagues (2011) monitored 103 consecutive free flaps performed and found that the remote smartphone photography assessment had a comparable accuracy rate (94.2%) as with in-person examination (98.7%), and shorter response time to re-exploration of the flaps, if needed (due to decrease in perfusion of the flaps).

Wani and colleagues (2013), from the King Fahad Medical City in Saudi Arabia assessed the efficacy of smartphone and its WhatsApp (Santa Clara, California), the instant short message service application for smartphones which allows creation of groups and sharing of real time text messages, pictures and videos, as a communication method amongst staff. The researchers found that this method was effective for patient care and academic endorsement, and suggested that it could be used for management of trauma and disaster to start pre-hospital management.

2. Mobile Phones used for Teleconsultation in the Assessment and Management of Burn Wound Injuries

Victims of burn injuries might require admission in burn centres or units, with highly specialized professionals participating in an interdisciplinary team. In parts of the world with few and relatively inaccessible burn centres, particularly in low-and middle-income countries, traditional telemedicine has shown a positive influence in burn injury management (Turk, Aydogan, Oguz, Tarim, Karakayali & Haberal, 2010; Bezuhly & Fish, 2012; Syed-Abdul et al., 2012). In military setting, traditional telemedicine has shown to improve the triage of burn patients from remote environments to rear-based specialists (McManus, Salinas, Morton, Lappan & Poropatich, 2008).

The severity of burn injuries is determined by the percentage of the total body surface (TBSA) injured, depth of the burn, age of the patient, the presence or absence of inhalation injury and whether other co-morbidities are present. The TBSA burned and the depth of the burn wound are assessed mainly by visual inspection, and this is influenced by the experience of the health professional who examines the victim. The appearance of the burn wound plays an important role in the selection of emergency treatment, need for surgery, type of dressing or the need for referral to the next level of care. The telephonic discussion between the referring facility and the burn expert may lack important clinical information, which may result in less than optimal treatment. Therefore, the inclusion of a digital/coloured image of the burn wound is helpful and almost mandatory for correct burns assessment: the receiving clinician will be able to validate any information given over the phone, as well as additional information may be captured from the images supplied, improving the communication between the parts involved in the patient's management (Wallace, Smith & Pickford, 2007; Giaquinto-Cilliers, 2013).

Saffle (2006), from the University of Utah, United States, acknowledged that the referral of inappropriately assessed burn cases to specialized centres will increase due to several factors. These factors include increased public awareness, the related liability adding pressure on less resourced settings and less experienced doctors with burn assessment and management. A single photograph of a burn wound taken and sent through a cell phone would minimize the unnecessary and expensive transportation of minor burn injuries and would thus also allow the feedback from the specialist centre supporting the decision to transport a significantly burnt patient for proper treatment.

Shokrollahi, et al. (2007), from the Welsh Burns Centre, United Kingdom, assessed 31 minor burns (less than 10% of TBSA) and showed that the extent and depth of the injuries could be accurately estimated with the use of a 1-mega-pixel camera integrated into a mobile phone. The authors also suggested that with the rate of technological advances, especially with mobile phones, this telemedicine modality might have exciting benefits in future times.

Knobloch, Rennekampff and Vogt (2009), from the Hannover Medical School, in Germany, discussed over digital images taken from two burn patients with a 5 mega pixel camera incorporated to a cell phone the immediacy and accuracy of the MMS transmitted images. The authors of this study stressed that a burn consultant, irrespective of his or her geographic position within the hospital, abroad or at home, after-office hours may be reached for discussion about the appropriate treatment to be given to a particular patient; this would increase patient's safety through the use of expertise consultation. Also, the JPEG images obtained by the phone camera could be easily stored in a hardware system for patient's documentation via the camera card, which is important for legal cases.

Wallace, Hussain, Khan and Wilson (2012) from Birmingham, United Kingdom, undertook a systematic literature review dating from 1993 till 2010 using visual images of 24 chosen articles.

The researchers discussed feasibility, clinical validation and cost effectiveness of the studies. They have confirmed that the current mobile phone technology provides resolution superior to the earliest telemedicine programmes and that interactive dynamic systems are now the technology, that is currently in mobile phones as single touch applications. These factors made them anticipate a growing number of case reports for the use of mobile phones for interactive burn assessment, although legal concerns and data protection still needs to be addressed. Furthermore, the researchers made a point that some static and video services provided encryption, which is needed for data protection (e.g. Skype™).

Atiyeh, Dibo and Janom (2014) reviewed the available literature about telemedicine and burn injuries however only two systematic reviews of the literature were found revealing a limited number of relevant published papers on this topic.

3. Mobile Phones Used as Other Resources by Plastic Surgeons

The use of mobile technology by healthcare professionals in the healthcare setting has gained popularity with the availability of several smartphone applications ("apps") specifically developed to aid clinicians from all medical specialties. As plastic surgery is per definition a speciality that must be up front with innovation and creativity, plastic surgeons have been encouraged to apply the latest technology offered by handheld devices.

Amin and colleagues (Amin, 2011; Amin, Edmonds, Abboudi & Sivakumar, 2012), from St. George's Hospital and Royal Free Hospital School of Medicine, United Kingdom, have pointed out that there are fewer applications currently on the market developed for plastic surgeons (senior and trainees), in comparison with other medical specialties. Freshwater (2011) and Molajo, Vaiude and Benson (2011) suggested that other non-specific apps (such as Body Mass Index- BMI- Calculator, updated information on medications, emergency guidelines, comprehensive medical calculators

and scores) might also be used by the plastic surgeon. Both groups suggested free and paid apps useful for the speciality, amongst them: anatomy apps, guidelines for open fractures of the lower limb (leg trauma), plastic surgery glossary, and apps from plastic surgery journals and scientific societies.

Although not specific for plastic surgeons, Mosa, Yoo and Sheets (2012), from the University of Missouri, USA, performed a systematic review of published articles discussing healthcare applications for smartphones to be used by healthcare professionals and patients.

Workman and Gupta (2013), from the Loma Linda University School of Medicine, reviewed the smartphone applications related to plastic surgery after an online search through all available markets (app stores) and classified the available applications (161 from the Apple's app store) in the following categories: practice or surgeon-based apps (54); academic-based apps (23); patient-based apps (10) and non-applicable apps (27). The majority of surgeon/practice-based apps involved opportunities for cosmetic surgeons to market their practice. Academic-based apps offered access to abstracts, papers, and other scientific content, although few specifically useful to plastic surgeons or opportunity for education. Patient-based apps provided education to patients in search of plastic surgery, while non-applicable apps usually involved creative photo morphing not important to plastic surgeons.

Al-Hadithy and Ghosh (2013), from the United Kingdom, also performed a review of the current use of smartphones and future developments for the practising and in-training plastic surgeons. The researchers presented a list of useful smartphone applications and mobile versions of websites (no need for apps download). They discussed the availability of podcasts (series of digital, audio or video files that are released episodically and downloaded via internet) and videos demonstrating online surgical procedures and clinical examinations through sites such as You-Tube, which are useful for in-training plastic surgeons

and the availability of plastic surgery textbooks in ebook versions reached through the smartphones.

A pilot study was launched in Brazil by Valente, D.S., Eifler, L.S., Carvalho, L.A. (2014) with the objective to demonstrate an experience of telemedicine in Plastic Surgery. The study entailed the real time streaming of a surgical procedure to 32 Plastic Surgeons and then to determine, whether or not, they would be able to perform it; 92,6% felt that they would be able to do the surgery demonstrated. Telemedicine thus provides additional access to education for Plastic Surgeons who seek medical education from more distant and isolated regions.

Dunne and Rawlins (2013) reviewed smartphone applications relevant to burn care and found it limited, and suggested the development of more applications educating on early burns management for the public and healthcare professionals.

There are currently a number of software applications for mobile phones with the purpose of supporting the management of burn injured patients. These include the BurnCare app by Pierre-Antoine Meley; BurnMed by Johns Hopkins Mobile medicine; LiAo Burns by Omesoft; uBurn by JAMB and MerseyBurns by St Helen and Knowsley Teaching Hospitals. With the exception of the latter two, very few of the applications available have been validated or described in scientific literature.

More recently Wallis, et al (2016) developed a smartphone application and cloud-based consultation system for burn injury emergency care, aiming to be different from the pre-existing mobile applications by providing actual consultation from a burn expert.

Grover (2013) added to the findings that the use of smartphones had the opportunity to reach, market to and educate potential and existing patients through non-practice related social media applications, such as Facebook, Twitter, YouTube, LinkedIn, Pinterest, and Tout. Through mobile phone use the plastic surgeon could update potential patients about the latest news, trends and topics in plastic surgery; invite patients to

upcoming educational seminars (particularly in cosmetic surgery) and post procedural videos and patient testimonials – a change in behaviour from a few years ago. This participation in social media is also discussed by Wheeler, Said, Prucz, Rodrich and Mathes (2011), Larson (2011) and Camp and Mills II (2012),

Even scientific and peer-reviewed journals for the speciality, professional societies and publishers in the field have joined the social media platform available in mobile phones through Facebook and Twitter (and foreseeing new platforms, such as Tumblr and Google Plus), to reach readers in a broader platform (plastic surgeons and ‘e-patients’) and interact with them; also, the new approach to social media has created a source for continuing medical education and best practices for the plastic surgery community/ world wide network (Rohrich & Weinstein, 2012).

Hughes, K. (2016) conducted a study with the goal to determine the feasibility of following up post-operative, plastic surgery patients, using only patient-taken images. The study highlighted the benefits for the management of patients who are separated from their surgeons due to geographic or financial constraints. This follow-up method ultimately led to a new management paradigm in the practices studied.

Other researchers have approached the use of mobile phone technology to create a ‘Telewound’ network for chronic wounds (Braun et al., 2005) and the home follow-up of patients undergoing ambulatory surgery (Ramos, Cerdan & Lopez, 2009). Even studies exploring Telewound care, and its use in home care settings with traditional telemedicine systems, have discussed the future migration of these systems to mobile phones devices, stimulated by prototypes of mobile systems in development that use spectral analysis to detect the presence of bacteria within a chronic wound (Santamaria & Kapp, 2013).

There is a general agreement that smartphone technology creates channels that are here to stay, and the behaviour of plastic surgeons has considerably changed since the conception of the first

smartphone. This behaviour has lead to the creation of new social media guidelines, addressing the benefits and drawbacks of online interaction, and proposing safeguards to avoid ethical risks (Kling, 2013).

Suliman M.T., from the King Khalid Civilian hospital in Saudi Arabia reported in 2013 that by using the WhatsApp service he was able to save patients’ travel expenses and treatment time by reducing the need for additional consultations after receiving images of a scar for review by a remotely located physician.

Aspects of consent amongst members of the Canadian Society of Plastic Surgeons were reviewed by Chan, N., Charette, J., Dumestre, DO. & Fraulin (2014). She determined that amongst 142 respondents, 75% believed that obtaining verbal consent before taking clinical photographs on a smart phone was sufficient to ensure the privacy rights of the patient were respected. Additionally, 72% of respondents felt that obtaining written consent for each patient prior to taking photographs was impractical. She concluded that smart phones are convenient and when password protected offer adequate security to ensure the privacy of the patient.

FUTURE RESEARCH DIRECTIONS

Traditional telemedicine systems using store-and-forward or real-time equipments are expensive and difficult to set up and require ongoing maintenance costs, while mobile phone messaging is comparatively cheaper and easier to use, with more portability and mobility. Limitations for the use of tele-technology include: poor infrastructure, limited equipment availability, and insufficient access to training and education for medical personnel, particularly in settings with poor resources as suggested by Lewis, Thomas, Wilson and Mbarika (2012).

Earlier studies have used relative ‘old’ mobile phone technology, where the quality of images (size and resolution) generated by small screen

probably showed much lower resolution than the current images offered by the new generation of smartphones; nevertheless, the results were promising. Definition even in small screens, and the use of mobile telemedicine will be more attractive to the specialty, with decrease in misinterpretation of the images. The transmission of videos showing full assessment of the function of the affected part of the body under examination (e.g., the hand movement) will add more value to future studies, although transmission time may vary according to the service provider. Also, 3D technology incorporated to cell phones will allow better assessment of wounds, and images will bring more information that is missed through the flat transmission currently obtained.

Currently, about 90% of handset sales worldwide are for devices powered by Google's Android (Samsung, HTC, Motorola, LG) and Apple's iOS mobile (iPhone) operating systems (Smartphone, 2014). Accessing the smartphones market stores now in search for applications for plastic surgery with terms such as *plastic surgery*, *cosmetic surgery*, *reconstructive surgery* and *burns* will display a crescent number of available apps compared with the previous published studies (Apple, 2014).

Patel, NG., Rozen, WM., Marsh, D. (2016) described the use of smartphone applications in the peri-operative management in microsurgical breast reconstruction in the United Kingdom. Though no single ideal plastic surgery application was found, multiple general applications were highlighted that could prove useful for use in microsurgical breast reconstruction. Applications were grouped into those used for efficient communication, storage, education and flap monitoring. Patel concluded that the future of smart devices lies in wearable devices able to monitor clinical condition and provide real time feedback where needed. Application development for the smart watch is seen as the start of this new revolution.

Future development of mobile applications for the specialty should also incorporate expert

knowledge of plastic surgeons to the development of specific software for the specialty (Amin, 2011; Workman & Gupta, 2013). Applications designed to collect data for research with the transfer of data electronically to a centrally based computer, described for other specialties (Tomlinson, 2009) should also allow research in certain fields of plastic surgery, particularly where epidemiological data is important, such as with burn injuries. The potential for using smartphones for data collection has been explored by Hundeshagen, Weissman, Farber, Winkler and Haik (2013).

WhatsApp (WhatsApp Inc., Mountain View, California, USA) is a cross platform, cost-effective mobile phone communication application facilitating the exchange of instant messages, pictures, videos and voice calls over the internet between two or more individuals simultaneously. The advantage of using a cheaper messaging platform is ease of access. As of 26 February 2016, one billion people around the world use WhatsApp.

The application allows in group text format multiple members to participate in a single ongoing discussion. This serves as an additional teaching platform as well as allowing input from multiple senior colleagues either within normal consultations, the operating room or after hour consultations. Fernandez-Valencia, JA., Egea, J., Pinyol, MC., Orench, M. (2015) explored the use of a WhatsApp group in aiding the coordination of a multidisciplinary surgical team. After eight months 830 messages were posted and constituted 177 conversations relating to operating room occupancy, operating schedule, prosthetic materials, patients' clinical issues, surgical information and miscellaneous topics. He concluded that instant messaging services such as that provided for by WhatsApp can be used to optimize patient care.

CONCLUSION

The integration of the mobile phone technology into wider practice will depend on clear regulations

set by official statutory bodies addressing patient's confidentiality and safer use of transmitted images and data. Medico legal issues, medical malpractice and security concerns must be addressed in a constructive way to enable integration of this tool into wider practice; through anonymising all data transferred, documenting the patient's consent, and keeping patient's confidentiality by an adequate and safe use of the images obtained (one phone available for the receiving unit), a par with the current regulations provided by the country's official organizations (Shokrollahi et al., 2007; Mars & Jack, 2010). Smartphones designed entirely around security, encryption and identity protection will address this issue in a near future. Smartphones, as well as standard mobile phones, may be stolen and security functions overridden allowing breach of confidentiality with the exposure of all data stored in the portable device.

There is a large potential clinical application for the use of mobile phones and their sophisticated resources as a telemedicine system in countries which lack human resources, distances between specialized centres are a real concern, and costs play an important factor in the health system (Giaquinto-Cilliers, 2013). The growing numbers of studies in recent years has shown the interest of plastic surgeons within this topic.

Above all, the validation of the increased value added by this 'cheaper' telemedicine system, as for the traditional system, must be constantly assessed by further researches, taking into consideration the acceptance and satisfaction of the patients, costs involved, infra-structure, and technical skills. Face-to-face interaction with the specialist is beneficial, and must always take precedence over other systems; but the current technology used to help where resources are scarce will definitively add value and possibly decrease costs in the initial management of the patient in need of plastic surgery.

KEY TERMS AND DEFINITIONS

Burns: Injury of the skin caused by heat,
electricity, chemicals, friction or radiation.

**Mobile Phone/s and Mobile Phone Technol-
ogy:** Handset phone that can make and receive
telephone calls while moving around a wide
geographic area.

Mobile Telemedicine: Use of mobile device-
s for consultation at a distance.

Photo Messaging: Transmission of pictures
through mobile phones.

Plastic Surgery: Specialized branch of sur-
gery that aims to restoring the form and function
of the skin and underlying structures affected by
traumatic injuries, burns, congenital abnormali-
ties, and losses caused by infection, tumours or
cancer excision.

Reconstructive Surgery: Sub discipline of
plastic surgery.

Smartphone(s): Mobile phones with more
advanced computing capability and connectivity
than basic feature phones.

Smartphone Application: Software pro-
gramme designed to run in smartphones and other
mobile devices.

Telemedicine: Delivery of health care services
at a distance by health care professionals using
information and communication technologies for
diagnosis, treatment and prevention of disease and
injuries, research and evaluation, and continuing
education of health care providers.

The Intersection of Religion and Mobile Technology

M**Wendi R. Bellar***Texas A&M University, USA***Kyong James Cho***Texas A&M University, USA***Heidi A. Campbell***Texas A&M University, USA*

INTRODUCTION

The proliferation of mobile technology throughout society has influenced many aspects of contemporary life, including religious practice. While much scholarship is focused on religious mobile applications (apps), earlier scholars also explored how different religious groups adopted, negotiated, or rejected mobile technology according to their core values and beliefs. Research on the intersection of mobile technology and religion falls under studies of “digital religion,” which seeks to understand the complex relationship between digital technology and religion (Campbell, Altenhofen, Bellar, & Cho, 2014). Broad themes explored within digital religion over the last 20 years include religious authority, identity, community, and authenticity (Campbell et al., 2014). These research themes help reveal the ways religious individuals and communities engage with both mobile technologies and digital culture as a whole.

This article is divided into three sections. First, a brief background on studies of mobile technology and digital religion provides necessary context for understanding the history and trajectory of religion and mobile studies. Next, three key areas of religion and mobile media research are explicated: how religious individuals and communities negotiate mobile media use, the ways in which religious mobile apps are being designed and used for religious practice, and the commodification

of religion through mobile media. Finally, the article concludes with a discussion of emerging trends within mobile media and religion, which suggests future research opportunities.

BACKGROUND

Mobile media have been described as “unanchored communication” which takes place “during transition” (S. Campbell, 2013, p. 10). It is important, however, to distinguish between laptop devices and mobile devices. While laptops can move from place-to-place, the proper infrastructures, from physical space to wireless internet connections, are required for use. Mobile devices, however, can be used anytime, anywhere. Additionally, the diffusion of mobile devices throughout the developed world raises concerns and inquiries about their social and cultural impacts (Smith, 2013), such as the positive and negative impacts mobile technology can have on religious communities.

In the US and other developing countries, mobile phone penetration has almost reached saturation point and smartphone adoption is increasing rapidly (“2 billion consumers”, 2014). Recent surveys also provide a clearer picture of mobile app use. Neilson (2015) found apps account for 89% of mobile phone usage, while 11% can be attributed to the mobile web. In the US, the average smartphone user has approximately 28 apps

DOI: 10.4018/978-1-5225-2255-3.ch535

downloaded on their devices and has used 11 of those apps within the last month (Google, 2015).

While religious mobile use is not reflected in these numbers, other studies point to religious engagement through mobile technology. For example, religious engagement online has been well documented since the 1980s (Campbell, 2010). Sixty-four percent of Americans reported searching for religious information or engaging in religious practice online (Hoover, Clark, & Rainie, 2004). The Barna Group reported that one in four Christians uses an e-reader or other mobile device for reading the Bible (2013). That same report showed that pastors' use of mobile technology to read and study the Bible tripled in two years to 44% (Barna, 2013). While it is clear mobile technology is being used for religious purposes, the impact this mobile technology use is having on religious users and communities is underresearched.

Numbers on the diffusion of mobile technology in general, and in religious contexts, highlight the need for careful study of the ways in which these technologies influence religion and how religious users engage mobile technology. This brief review of statistics implies the intersection of religion and technology follows similar patterns as mainstream adoption and use. Yet in their work digital religion scholars emphasize mediating factors such as specific beliefs, core values, and ritual practices that contribute to unique forms of engagement (Campbell, 2010). Therefore, digital religion seeks to understand these unique engagements, to illuminate the broader relationship between technology and religion as a whole.

Digital Religion

Digital religion is defined as a “framework for articulating the evolution of religious practices online which are linked to online and offline contexts simultaneously” (H. Campbell, 2013, p. 1) Research on mobile technology and religion is a subfield of digital religion in that: a) mobile technologies are providing a new way for prac-

ticing religion; and b) those religious practices happen concurrently in multiple online/mobile/offline contexts While early studies of religion and media contextualized the online and offline as separate spaces, digital religion argues for a “third space” in which the two are blurred (Hoover & Echchaibi, 2012). Mobile users and religious contexts occupy these two spaces simultaneously in everyday life.

Studies on religion and the internet began two decades ago (for more detailed accounts see additional reading suggestions). Religious authority, community, identity, and authenticity have been major themes within digital religion (see Campbell et al., 2014). The development of the field can be described as flowing through four waves: a) a focus on describing new opportunities online spaces provide for religious practice and the potential impact technology has on religious understanding (H. Campbell, 2013b, p. 8); b) an exploration of technologies and users practicing and engaging religion in online spaces through questions about religious identity, authenticity, and practice (H. Campbell, 2013b, p. 8); c) theoretical and interpretive research on how the “embeddedness” of the internet in everyday life influences religious digital practice” (H. Campbell, 2013b, p. 9-10); and d) a focus on new methodological modes, as well as development of typologies and categorizations for interpretive purposes (Campbell & Lövheim, 2011, p. 1092). Mobile technologies are a focus within this fourth and current wave.

KEY THEMES IN RELIGION AND MOBILE TECHNOLOGY

This section discusses the latest research in three key areas of religion and mobile technology studies: religious communities and individual engagement with mobile technology; the design, development, and use of religious mobile apps; and the commodification of religion related to mobile technology. Each section provides a broad overview of the current and research available pro-

viding important information toward identifying gaps and evaluating promising future directions.

Accepting, Rejecting, and Negotiating

While religious communities have historically evaluated new technologies (e.g., the printing press and electronic media) and their potential impacts on religious life, mobile technology's multiple modalities present a unique case. Access to information, media content, and communication in real time helps meet religious goals or needs, and also causes concern for potential negative outcomes. Generally, religious communities have three responses when evaluating new technology: accept and justify technological affordances as tools to meet religious requirements, reject and frame technological affordances as problematic or evil, or acknowledge both good and bad technological affordances and negotiate rules for proper use (Campbell, 2010).

When religious communities and members advocate for mobile technology, they frame use as a tool for religious communication and practice. Mobile device affordances in this case align with the religious community's values. For instance, the ease and speed of communicating with others, as well as using mobile technology seen as "cool and hip" resulted in a positive outlook for a young group of Javanese Muslims (Barendregt, 2009). Ease and speed of communication were also used as a justification for Pentecostal Christian Church members to embrace mobile use (Togara-sei, 2012). Filipino Christians used mobile SMS texting to communicate religious and inspirational messages, particularly around religious holidays (Roman, 2006). Similarly, mobile affordances allowed Jamaican church members to keep in touch with other members and coordinate church related events (Horst & Miller, 2006). These cases demonstrate how mobile technology affordances were framed as tools to help the community meet both religious goals and the need to stay in touch and coordinate religious meetings and rituals.

Religious leaders and members frame inappropriate mobile technology as harmful or even potentially evil. Access to pornography through mobile internet is of particular concern to many religious groups (Barendregt, 2009; Roman, 2006). In these instances, mobile affordances do not help meet religious objectives and undermine core religious values and beliefs (Campbell, 2010). A backlash against mobile use within the Muslim community pointed to the tension between religious beliefs and practices and unwanted shifts in cultural values. When this happens "...members are more likely to unite and speak out against the technology (Campbell, 2006b, p. 142).

Generally, religious communities discuss both positive and negative mobile affordances and negotiate rules to meet religious needs. The negotiation process leads communities to engage technology only in certain ways and contexts. For instance, using "correct" religious phrases to begin and end a text message is seen as proper etiquette within certain groups (Barendregt, 2009). Additionally, community members often negotiate their personal use of mobile technology outside the recommended rules given by religious authorities. Cohen et al. (2008) found young Haredi Jews maintained personal rules for mobile use in private, but adhered to the religious communities' rules of use in public (Cohen, Lemish, & Schejter, 2008, p. 98). Richardson and Pardun's (2015) study showed rules are created for specific religious contexts. Their survey of highly religious Baptist users in the southern US revealed individuals' excitement and confidence in their personal religious use of mobile technology, but concern for the possible distraction mobile devices cause in public worship.

While religious users in previous examples negotiated proper use of the technology for specific contexts, other communities decide to reshape the technology as whole to meet their religious needs. Campbell's (2010) religious social shaping of technology (RSST) framework allows researchers to explore this by focusing on a given group's history and traditions, as well as their core values and patterns. These factors played a role,

for example, in Ultra-Orthodox Jews' negotiation of the mobile phone. As originally designed, the mobile phone conflicted with Ultra-Orthodox Jews' unique social boundaries and needs, because it allowed access to problematic content through internet and texts. The reshaping of the mobile phone as a "kosher" phone blocked this content and was framed by religious leaders as a righteous symbol against secular, immoral forces. This reframing of the technology to fit within a more traditional framework made it acceptable to religious authorities.

Acceptance, rejection, and negotiation with specific mobile technologies depend upon their use, context, and alignment with religious communities' unique values and goals. Therefore, a group's history of media use, religious values, and patterns of practice play a vital role in their negotiated use of technology. Therefore, RSST offers a useful approach for scholars studying these phenomena.

Religious Mobile Apps

Religious mobile apps, defined as small software applications designed for use on mobile devices specifically for religious purposes, are the fastest growing research foci within digital religion. Research in this area falls into two categories: religious app design and development, and religious app design and use. Design and development studies generally use textual and content analysis of the apps themselves. Only one study within digital religion collected data directly from developers (Hutchings, 2014). Most studies within the last two years have focused on user intentions and motivations and user-experience design research used to test individual religious apps.

- **Religious App Design and Development:** Studies in this category investigate the apps themselves in order to gain insight about their type and scope, and also to interpret how religious app affordances translate into specific outcomes for users and com-

munities. Wagner (2013) and Campbell, Altenhofen, Bellar, and Cho (2014) created categories and typologies of religious apps, respectively. Wagner (2013) highlighted six categories of religious apps on iTunes, including prayer, ritual, sacred text, and religious social media apps. Her analysis also focused on how apps impact users' religious identities. She concluded the personal nature of religious apps as far as choice and use allows individuals to create their own understandings apart from the structure and rules of traditional religious authorities.

Wagner's (2013) categories helped lay the groundwork for Campbell, Altenhofen, Bellar, and Cho's (2014) systematic categorization of more than 400 religious apps available on iTunes, which resulted in a typology of 11 diverse categories defining different religious app use (Campbell et al., 2014, p.163). Their analysis resulted in two parent categories: apps oriented around religious practice, which help facilitate traditional religious practices or experiences like prayer, and apps embedded with religious content that provide religious information or materials, but do not necessarily facilitate religious practices or rituals. Subcategories for religious practice apps include sacred textual engagement, prayer, focus/meditation, devotional worship, and ritual. Secular app counterparts may be readily identified—e.g., music players that provide both religious and secular content. Subcategories for religious content apps included religious utilities, religious wisdom and leaders, religious media, religious games, religious apps for kids, and religious social media.

Other studies on app design and development analyzed how the affordances of the device and apps themselves influence religious practices and understandings. An earlier study by Torma and Teusner in 2011 explored the intersection of cultural and social values associated with the iPhone and religious values and beliefs. Their study narrowed in on affordances of connectivity,

audio-visual, and the private and personal nature found in app user interfaces and content. They concluded that for religious apps to be meaningful to users, developers needed to take advantage of audio and visual affordances to create interactivity and engagement. Wagner and Accardo (2014) similarly noted the personal and individualized nature of Buddhist apps and their connection to the westernization of Dharma. Their approach is reminiscent of technological determinism, which posits that the medium directly affects use: "... when we study Dharma embedded and communicated in the context of portable devices, it can indeed be shaped by its environment" (Wagner & Accardo, 2014, p. 137). However, they note user attitude will also affect religious app use and effectiveness. Other noted effects include mixing the profane with the sacred, and the fact that the isolating and personal nature of apps changes the value Buddhists place on communal practice. While this approach suggests a direct influence of apps on religious practices, current work focuses on how users negotiate and possibly reshape apps to avoid effects that do not align with their religious values.

As mentioned earlier, only one study collected data directly from app developers—Hutchings's (2014) case study of the Bible App developed by LifeChurch.tv, a mega church based in Oklahoma, USA. He concluded that app designers used specific features (i.e., social media and reading plans) to guide users' Bible reading in specific ways. Therefore, app developers and designers are either already traditional religious authorities, or become a type of religious authority through employing or not employing specific affordances in app design. This is in contrast to Wagner's (2013) conclusion that individual users will determine their personal practice outside the purview of religious authorities.

This overview shows scholars have studied religious apps and their affordances to either create app typologies or to link affordances with possible religious outcomes such as practice. Yet it is important to note an app's affordances

do not guarantee individuals will use the app in intended ways.

- **Religious App Design And Use:** Other researchers focus on religious app users in conjunction with, or in addition to, the apps themselves. One of the earliest apps studies designed an app for use in Muslim prayer and evaluated user engagement (Wyche, Caine, Davison, Patel, Arteaga, & Grinter, 2009). Similar to Torma and Teusner's (2011) conclusion that audio-visual cues are important for meaning-making in religious apps, Wyche et al. found Muslim users embraced the app because of its use of imagery in the app design (i.e., nature and the sun, simple pictures of mosques). Participant interviews revealed images—the placement of the sun on the background of the app, and images of mosques—made users feel connected to the larger Muslim community and the analogue understanding of prayer.

Bellar (2016) used the concepts of networked identity and networked community (Campbell, 2012) to analyze how religious app use influenced Evangelical Christian users' identities. Findings showed participants were more likely to choose religious apps that already aligned with their core religious practices, such as reading the Bible. When the app met religious expectations, it reinforced participants' religious identities, but their identities were negatively impacted when those expectations were not met. Second, findings showed participants used their religious networked community to choose religious apps. The private, personal nature of religious app use influenced the ways in which users were comfortable sharing with others.

Hutchings (2015) conducted an online survey of UK and US digital Bible readers and found five positive effects of app use: convenience, easy access, easier to study, engagement with other readers online, and more consistent reading

practices. Negative aspects of app use were: the sacred status of the Bible was diminished, verses and passages were more likely to be read out of context, and there was a “loss of meaningful relationship to the printed Bible” (Hutchings, 2015, p. 15). Similarly, Richardson and Pardun (2015) found that highly religious Baptist app users were concerned with convenience but worried about possible distractions app use in public worship cause. Additionally, their user survey and focus groups revealed a hesitation to replace the physical Bible with digital text, because the printed book was related to important memories and allowed tactile engagement through underlining, highlighting, and taking notes.

Lechebusch, Kowalewshi, Lidynia, and Ziefle (2015) compared Christian and Muslim adoption and use of religious apps in Germany. Their focus groups and survey data showed that Muslims were more likely than Christians to use religious apps. Both groups were interested in using apps with access to holiday calendars, religious quizzes, information on proper social app use, and information about religious history. Findings also showed Muslims were more likely than Christians to use digital prayer beads on a mobile app. Additional comparative studies are needed on different religions and regions to gain a more holistic picture of religious app adoption and use.

Finally, user-experience researchers have been involved in designing and testing apps for religious use. These studies highlight the need for more interdisciplinary research in this area. For example, five studies over the last two years used Human and Computer Interaction (HCI) approaches. These have focused on Muslim and some Christian engagement—use of Islamic apps by the elderly (Ahmed, Zainal, Razak, Adnan, & Osman, 2015), using accelerometer functions to monitor correct prayer postures for Muslims (Al-Ghannam, Kanjo, & Al-Dossari, 2016), intentions to use a pilgrimage app for Spain’s Camino de Santiago (Attunes & Amaro, 2016) evaluating appropriate design affordances using Near Field Communication for Muslims’ Hajj pilgrimage

(Mohandes, 2015), and development and use of a religious education app for Indonesian Muslim youth (Siadin, Mohamed, Adzmi, & Azhar, 2015). These studies highlight technological skills used to create engaging affordances for different religious users, and how creating user tests helps evaluate app success. Digital religion scholars would benefit from working with scholars in HCI in order to accurately understand design processes. Conversely, HCI scholars would benefit from collaboration with digital religion scholars in evaluating and understanding how religious groups’ core values and beliefs drive engagement with technology.

RELIGIOUS MEANING-MAKING IN MOBILE CULTURE

A third theme in mobile media and religion research has focused on the intersection of religion and consumer culture, or how people connect notions of religion and spirituality to mobile phone technology and culture. Fears of trivializing the sacred or falling into idolatry can cause a potential backlash against the commodification of religion (Barendregt, 2009; Togarasei, 2012). Consumer culture and religion are therefore often seen as antagonistic. Wagner & Accardo (2014) also noted the potential for downloads and advertisements to alter individuals’ perception of religious practice within capitalistic culture.

Another way these areas intersect is through the appropriation of religion into consumer culture, or selling products using religious elements. Robinson (2013) argues there is an intimate relationship between religion and technology. Technology companies such as Apple, for example, can become purveyors of spiritual ideals through design and marketing. Analysis of Apple advertisements showed that Steve Jobs’ spiritual-religious experiences informed his technological philosophy and subsequent approach to business and the design of Apple products, so that Apple technology is imbued with implicit religion.

It is not only developers who propagate religious devotion and meaning in their products. Users of Apple's Newton, a personal digital assistant (PDA) device that predated smartphones, rallied around the technology by creating a device narrative containing supernatural, religious, and magical themes (Muniz & Schau, 2005). Researchers assert that creating religious narratives around specific technologies points towards our impulse to believe in something outside of mundane reality, or, "it points to the inevitable intermingling of God and goods" (Muniz & Schau, 2005, p. 746).

Consumers, developers, and news media can co-create a cultural and religious symbolism that can build meaning around a particular technology. A good illustration is Gizmodo blogger, Brian Lam, who coined the term "Jesus Phone" in reference to the iPhone before the device even launched as way to frame it as revolutionary and even divinely inspired. Mac fans, critics, news media, and even Apple itself adopted this term to hype and critique the transformative power attributed to the device. Campbell & La Pastina (2007) assert consumers, bloggers, and critics appropriated the reference to Jesus to describe the transcendent nature of the iPhone that helped propel it into prominence in consumer culture. The Jesus Phone case study exemplifies the way technology like mobile phones can be imbued with greater cultural and religious meaning.

Mobile media, religion, and consumer culture intersect through the appropriation of religious elements by consumers and developers alike. Religious elements, such as references to Jesus or allusions to sacred narratives or themes, can act as a conduit for product creation or meaning-making. Because religious symbolism can be a deeply familiar resource from which to draw, mobile products can be imbued with implicitly sacred symbols, a fact that reveals how easily they can be mixed with religion in consumer culture.

EMERGING TRENDS AND FUTURE RESEARCH

Mobile media use by religious individuals and communities is a developing area within digital religion studies. This article highlights three primary ways scholars have approached the study of religion and mobile media: by looking at religious groups' and individuals' mobile phone use, by tracking religious app design and use, and by examining how the commodification of religion through mobile devices can manifest popular beliefs about religion. More research is needed in these areas to fully understand how mobile phones are impacting religious communities and users. Our observations lead us to note a number of important areas worthy of future research.

First, more refined theoretical understandings and methodologies are needed to illuminate religious engagement of mobile technology. Scholars can meet this need by applying theories and methods from communication studies, new media studies, HCI, and religious studies to mobile media and religion specifically, by developing and modifying theories based on research. Second, a more comprehensive overview of religious app development and use will aid further app development and act as a framework of study for future researchers. This includes the need to focus more on developers specifically, conduct more comparative studies of major and minor religions, and engage in interdisciplinary collaboration among researchers from media studies, HCI, and religious studies. Third, examining the appropriation of technology to reinforce or undermine traditional religious authority and structures will lead to more definitive answers about the impact mobile technology is having on religion. In this area it is important to examine access to information outside of traditional religious authority. Fourth, a further synthesis of the study of mobile media with broader religious activities will yield a more comprehensive overview of the use of mobile

media for religious purposes. Helpful starting points are key themes within the current study of digital religion work: ritual, identity, community, authority, authenticity, and religion (outlined in Campbell, 2013).

CONCLUSION

Investigating the relationship between religion and mobile media is an emerging area of study within digital religion. Research has yielded insight into how religious individuals and communities respond to mobile media, including what they see as positive and negative uses, and how/if groups create specific guidelines and rules for use; some preliminary pictures of the religious mobile landscape; and the connection between religion and consumer culture through mobile media. Because religion interacts with many social, political, economic, technological, and global factors, research demands continued theoretical development and nuanced study.

KEY TERMS AND DEFINITIONS

App Developers: Individuals, religious groups, and secular companies who design and produce mobile apps.

Apps: Small computer programs designed for use on mobile devices.

Commodification: Transferring religious information or practices into commodities to be bought and sold, and using religious narratives to sell secular goods and services.

Digital Religion: The study of the evolution of religious beliefs and practices at the intersections of online, mobile, and offline contexts.

Mobile Devices: Cell phones, smartphones, and tablets that provide the infrastructure to communicate and access content anytime, anywhere.

Religious Communities: A group of people who adhere to specific beliefs and practices that relate to the sacred.

User-Experience Design: A research approach that explores the interaction between design and use with the goal of increasing usability, accessibility, and pleasure.

Methods for Simultaneous Improvement of Comb Pass Band and Folding Bands

M

Gordana Jovanovic Dolecek
Institute INAOE Puebla, Mexico

INTRODUCTION

Decimation is a reduction of a sampling rate in a digital form by an integer, called decimation factor. It consists of two stages: filtering and down sampling. Practically the sampling rate is decreased only in the second stage, called down sampling (Harris, 2004). However, during this process, the replicas of the main signal spectrum occur. If the signal is not properly filtered before down sampling, the overlapping of the repeated replicas of the original spectrum, called aliasing, may occur. The aliasing may destroy the useful information of the decimated signal and must be eliminated by the filter which proceeds the down sampling, called decimation filter.

The most simple decimation filter is a comb filter which has all coefficients equal to unity, and consequently does not require multipliers, (Hogenauer, 1981). The transfer function of comb is given as:

$$H(z) = \left[\frac{1}{M} \sum_{k=0}^{M-1} z^{-k} \right]^K, \quad (1)$$

where M is the decimation factor, and K is order of the filter.

Note that all filter coefficients are equal to unity. The comb transfer function (1) is also known as non recursive form. An equivalent transfer function, also known as a recursive form, is given as:

$$H(z) = \left[\frac{1}{M} \frac{1 - z^{-M}}{1 - z^{-1}} \right]^K. \quad (2)$$

From the recursive form (2), a simple comb structure, called CIC (Cascaded-Integrator-Comb) filter, proposed by (Hogenauer, 1981), is obtained. It consists of the cascade of K integrators $1 / (1 - z^{-1})$ and K combs, $(1 - z^{-1})$ separated by a down sampler by M .

To preserve the decimated signal, the comb magnitude characteristic:

$$H(e^{j\omega}) = \left[\frac{1}{M} \frac{\sin(\omega M / 2)}{\sin(\omega / 2)} \right]^K, \quad (3)$$

must have a flat magnitude response in the pass band of interest, and high attenuation across the bands around the comb zeros, also called folding bands. However, comb magnitude characteristic exhibits a low attenuation in folding bands and a pass band droop in the pass band of interest, which may deteriorate the decimated signal. Increasing the order K , the attenuation in folding bands is improved, as shown in Figure 1, for $M=9$ and $K=1, 2, 3, 4$, and 5 .

However, the pass band droop is increased as illustrated in Figure 2, for the same parameters as in Figure 1.

Different methods are proposed for decreasing comb pass band droop, increasing the attenuation in the comb folding bands, and for both: simultaneous decreasing of comb pass band droop, and increasing folding band attenuation. The goal of this article is to present the principal approaches for the comb simultaneous pass band and stop band improvements.

Figure 1. Overall comb magnitude responses for $M=9$ and different values of K

Figure 2. Pass band comb magnitude responses for $M=9$ and different values of K

BACKGROUND

First, the comb pass band and folding bands are defined. Comb pass band is determined by the pass band edge ω_p , which depends on the comb decimation factor M and the decimation factor R of the stage which follows the comb decimation stage (Kwentus & Willson, 1997):

$$\omega_p = \frac{\pi}{MR}. \quad (4)$$

To this end, the comb pass band is defined for frequencies ω :

$$0 \leq \omega \leq \omega_p. \quad (5)$$

Depending on the value R , the comb pass band can be wide band ($R \leq 4$), and narrow band ($R > 4$). The zeros of comb are defined at:

$$\frac{2\pi k}{M}, \quad k = \begin{cases} 1, \dots, M/2 & \text{for } M(\text{even}) \\ 1, \dots, (M-1)/2 & \text{for } M(\text{odd}) \end{cases} \quad (6)$$

The comb folding bands are defined as bands around comb zeros:

$$\frac{2\pi k}{M} - \omega_p \leq \omega \leq \frac{2\pi k}{M} + \omega_p, \quad k = \begin{cases} 1, \dots, M/2 & \text{for } M(\text{even}) \\ 1, \dots, (M-1)/2 & \text{for } M(\text{odd}) \end{cases} \quad (7)$$

As an example Figure 3 shows the comb zeros and the corresponding magnitude responses for values of $M=6$, (M is even), and $M=7$, (M is odd). For $M=6$, there are $6/2=3$ comb zeros for $0 \leq \omega \leq \pi$, and three folding bands around the frequencies: $2\pi/6$, $4\pi/6$, and $6\pi/6 = \pi$. Note that for M is even, there is always a folding band around π . Similarly, for $M=7$, there are three folding bands around the frequencies: $2\pi/7$, $4\pi/7$, and $6\pi/7$.

Figure 3. Comb zeros and magnitude responses for $M=6$ and $M=7$

DESCRIPTION OF METHODS

Classifications

Knowing that the comb filter is a very simple filter, the methods for improving its magnitude responses should also be simple, desirable multiplier less. The methods can be divided into three main groups: Methods based on sharpening; Methods based on simple corrector filters; Methods that combine alias rejection methods and compensator design methods. In continuation are presented all three groups of methods and illustrated with examples.

Sharpening-Based Methods

The filters sharpening technique (Kaiser & Hamming, 1977) can be used for simultaneous improvement of both pass band and stop band characteristics of a linear phase FIR digital filter. The technique uses amplitude change function (ACF). An ACF is a polynomial relationship of the form $H_{sh} = f(H)$ between the amplitudes of the overall, and the prototype filters, H_{sh} and H , respectively. The improvement in the pass band, near $H=1$, or in the stop-band, near $H=0$, depends on the order of tangencies m and n of the ACF at $H=1$ or at $H=0$.

The expressions proposed by Kaiser and Hamming for the m^{th} and n^{th} order tangencies of the ACF at $H=1$ and $H=0$, respectively, are given as,

$$H_0 = H^{n+1} \sum_{k=0}^m \frac{(n+k)!}{n!k!} (1-H)^k, \quad (8)$$

$$= H^{n+1} \sum_{k=0}^m C(n+k, k) (1-H)^k,$$

where $C(n+k, k)$ is the binomial coefficient.

The values of the ACF for some typical values of m and n are given in Table 1, where H_{sh} is transfer function of the sharpened filter and H is the transfer function of the prototype filter.

The polynomial in the first row is a simple cascade of filter with itself, which improves only the filter stop band. Similarly, the polynomial in the second row improves only the pass band. In

Table 1. ACF polynomials for $m = 1, 2, 3$ and $n=1, 2$, and 3

m	n	H_{sh}
0	1	H^2
1	0	$2H-H^2$
1	1	$3H^2-2H^3$
1	2	$4H^3-3H^4$
1	3	$5H^4-4H^5$
2	1	$3H^4-8H^5+6H^6$
2	2	$6H^5-15H^6+10H^7$
2	3	$10H^6-24H^7+15H^8$
3	1	$-4H^5+15H^6-20H^7+10H^8$
3	2	$-10H^6+36H^7-45H^8+20H^9$
3	3	$-20H^7+70H^8-84H^9+35H^{10}$

third row is presented the simplest polynomial which improves both, pass band and stop band. Increasing the values of m and n the polynomials become more complex. That is why here are presented the polynomials only for values $m, n=1, \dots, 3$.

To illustrate the use of sharpening polynomials, one simple filter is designed by Remez algorithm (Mitra, 2010), taking the following specification: pass band frequency $\omega_p 0.1\pi$; stopband frequency $\omega_s = 0.3\pi$; pass band ripple $R_p = 0.1$ dB, and attenuation in the stop band $A_s = -40$ dB. The designed filter is a prototype filter $H(z)$ and its magnitude response is shown in Figure 4 with the solid line. Next, three sharpening polynomials from Table 1, are applied to the designed filter, and the following sharpened filters are obtained: H_1 (for $m=0, n=1$); H_2 (for $m=1, n=1$); H_3 (for $m=2, n=2$). The corresponding overall magnitude responses are also shown in Figure 4. Similarly, Figure 5 shows the corresponding pass bands for the prototype filter and the sharpened filters H_1 , H_2 , and H_3 .

Note that, for $m=0, n=1$ (filter H_1), only pass band of the prototype filter is improved, while the stop band is deteriorated. Taking $m=n=1$, both pass band and stop band are improved in the sharpened filter H_1 . Similarly, for more complex polynomial, ($m=n=2$) the improvement of both bands in the

Figure 4. Overall magnitude responses for different sharpening polynomials, defined by m and n in Table 1

sharpened filter H_3 is better in comparison with sharpened filter H_2 with $m=n=1$.

Sharpening Comb Method (Kwentus & Willson, 1997)

To improve simultaneously the comb magnitude characteristic in pass band and folding bands, the authors proposed sharpening technique using the simplest sharpening polynomial which improves both the pass band and stop band, i.e. $m=n=1$. The sharpened comb transfer function is given as:

$$H_{sh}(z) = 3H^2(z) - 2H^3(z) = H^2(z)[3z^{-\tau} - 2H(z)], \quad (9)$$

where $H(z)$ is a comb transfer function given in (1) and (2), and τ is the delay which prevents possible nonlinearity of the phase, i.e. 3 must be placed just in the middle coefficient of $-2H(z)$ in (9). Consequently, the filter $2H(z)$ must have the first-type symmetry, i.e. have an odd order,

(Mitra, 2010). Note that sharpened comb works at high input rate, thus consuming a high power.

As an example, consider $M=10$ and $K=2$. The cascade of combs with $M=10$ has the first type symmetry. However, taking $K=3$, the second order symmetry is obtained and the formula (9) cannot be applied.

Knowing that the integers 3 and 2 can be presented as sum of power of two, which can be implemented by shifts and adders, the sharpened comb is a multiplier less filter.

The magnitude response of the sharpened comb is given as:

$$|H_{sh}(e^{j\omega})| = \left| 3 \left[\frac{1}{M} \frac{\sin(\omega M / 2)}{\sin(\omega / 2)} \right]^{2K} - 2 \left[\frac{1}{M} \frac{\sin(\omega M / 2)}{\sin(\omega / 2)} \right]^{3K} \right|. \quad (10)$$

Figure 6 compares the overall, and pass band magnitude responses in a wide band, ($R=2$) of the prototype comb filter ($M=10$, $K=2$), and the sharpened filter.

Figure 5. Pass band magnitude responses for different sharpening polynomials, defined by m and n in Table 1

Figure 6. Overall magnitude responses and zoom in pass band magnitude responses for the prototype and sharpened combs

Note that the pass band droop is decreased in narrow band and attenuation in the folding bands is increased.

Different methods are proposed to improve the original sharpening method.

Two-Stage Sharpening (Jovanovic Dolecek & Mitra, 2005)

It is supposed that the decimation factor can be presented as a product of two integers:

$$M = M_1 M_2. \quad (11)$$

The decimation has two stages. At first stage is the comb with the following transfer function:

$$H_1(z) = \left[\frac{1}{M_2} \frac{1 - z^{-M_1}}{1 - z^{-1}} \right]^{K_1}. \quad (12)$$

Similarly, transfer function of the comb at the second stage is:

$$H_2(z) = \left[\frac{1}{M_2} \frac{1 - z^{-M_2}}{1 - z^{-1}} \right]^{K_2} \quad (13)$$

Next, in order to decrease power consumption, the sharpening is applied only on the second stage. The transfer function of the equivalent comb filter at high input rate is:

$$H_{sh}(z) = H_1(z) Sh\{H_2(z^{M_1})\}, \quad (14)$$

where $Sh\{\}$ means sharpening.

The corresponding magnitude response is:

$$|H_{sh}(e^{j\omega})| = \left[\frac{1}{M_1} \frac{\sin(\omega M_1 / 2)}{\sin(\omega / 2)} \right]^{K_1} \left\{ 3 \left[\frac{1}{M_2} \frac{\sin(\omega M / 2)}{\sin(\omega M_1 / 2)} \right]^{2K_2} - 2 \left[\frac{1}{M} \frac{\sin(\omega M / 2)}{\sin(\omega M_1 / 2)} \right]^{3K_2} \right\}. \quad (15)$$

Figure 7. Overall magnitude responses and zoom of pass band magnitude response for the prototype and two-stage sharpened combs

As an example consider $M=20$ and $M_1=4$ and $M_2=5$, $K_1=4$, $K_2=2$. Figure 7 shows the overall magnitude responses and pass band zooms ($R=2$) for the prototype comb ($M=20$, $K=2$), and the two-stage sharpened comb.

Different modifications of sharpening technique are proposed in literature with aim to improve magnitude characteristic o decrease complexity, like (Laddomada & Mondin, 2004), (Saravanan & Jayaprakasan, 2013).

Simple Corrector Filters-Based Methods

The methods use the simple corrector filters designed to simultaneously improve both: the pass band and stop band of comb filter.

Five Corrector Filters Method (Jovanovic Dolecek & Fernandez-Vazquez, 2013)

Five multiplier less corrector filters, for values of $K=1, \dots, 5$ are designed with aim to improve comb magnitude characteristic in both: pass band and folding bands. The choice of the corrector filter depends on the comb order K , taking values $K=1, \dots, 5$, and does not depend on the decimation factor. The corrector filter is used for even decimation factors and works at rate which is $M/2$ time lesser than high input rate. As a result, attenuation is improved only in odd folding bands. Additionally, a comb pass band droop is decreased such that the absolute maximum pass band deviation is less than 0.25 dB. The maximum number of adders is 16 for $K=5$, while the minimum is equal to 7, for $K=1$.

As an example, consider $M=12$ and $K=3$. The corrector filter has 12 adders and the following coefficients:

$$g(0) = g(11) = 2^0; g(1) = g(10) = 2^0; g(2) = g(9) = -2^1; g(3) = g(8) = -2^3; g(4) = g(7) = 2^0; g(5) = g(6) = (2^4 + 2^3). \quad (2)$$

$$= g(9) = -2^1; g(3) = g(8) = -2^3; g(4) = g(7) = 2^0;$$

$$g(5) = g(6) = (2^4 + 2^3). \quad (16)$$

The transfer function of the corrector filter is given as:

$$G(z) = \sum_{n=0}^{11} g(n)z^{-n}, \quad (17)$$

where the coefficients $g(n)$ are given in (16).

Figure 8 shows the overall and pass band magnitude responses for comb and corrected comb using the corrector filter (17). Note that the pass band droop is decreased, and the attenuation in folding bands is increased in all odd folding bands.

Methods that Combine Alias Rejection Methods and Compensator Design Methods

There are a number of methods combining the methods for alias rejection with the methods for compensator designs.

Two-Stage Combs with Narrowband Compensator Method (Jovanovic Dolecek & Mitra, 2010)

Two-stage combs with different orders, and narrowband compensator was proposed in (Jovanovic Dolecek & Mitra, 2010).

The overall transfer function at high input rate is:

$$H(z) = \left[\frac{1}{M_1} \frac{1 - z^{-M_1}}{1 - z^{-1}} \right]^{K_1} \left[\frac{1}{M_2} \frac{1 - z^{-M_2}}{1 - z^{-1}} \right]^{K_2} G(z^M), \quad (18)$$

where M_1, M_2 and K_1, K_2 are the decimation factors and comb orders of the first and second stages,

Figure 8. Overall and pass band magnitude responses for comb and corrected comb, $M=12$, $K=4$ 

respectively, and $G(z)$ is the compensator with the following transfer function:

$$G(z^M) = -2^{-(b+2)}[1 - (2^{b+2} + 2)z^{-M} + z^{-2M}], \quad (19)$$

where b is the compensator parameter which depends on K_1 and K_2 as shown in Table 2.

Additionally, the factor M_1 and M_2 are chosen to be close to each other in values with $M_1 \leq M_2$.

The frequency, in which the worst case attenuation A_c occurs, is defined as:

$$\omega_c = \frac{2\pi}{M} - \frac{\pi}{RM}, \quad (20)$$

where R is the decimation factor which follows the comb filter. Here is used $R=8$. The values for worst case attenuation are also shown in Table 2.

As an example, consider $M=20$ with $M_1=4$ and $M_2=5$. The desired minimum worst case attenuation is $A_c=-70$ dB. From Table 2 the following

parameters are chosen: $K_1=4$, $K_2=3$, $b=1$. Figure 9 shows the magnitude responses of comb, and two-stage compensated combs. The zoom in the first folding band is shown to confirm that the desired minimum worst case aliasing attenuation is satisfied. Similarly, the pass band zoom shows that the pass band droop is decreased in the two-stage comb filter.

Table 2. Parameters of design for given values of K_1 and K_2

(K_1, K_2)	b	Worst Case Attenuation A_c in dB
(2,2)	2	-46.5
(3,2)	1	-68.75
(4,3)	1	-92.25
(5,4)	0	-115
(6,4)	0	-139.34
(7,5)	0	-160
(8,6)	0	-184.186
(9,6)	-1	-205.75

Figure 9. Magnitude responses for comb and two-stage compensated combs

In continuation are mentioned some methods for improving pass band in the modified combs with an increased alias rejection. For example, in (Fernandez Vazquez & Jovanovic Dolecek, 2009) and (Fernandez Vazquez & Jovanovic Dolecek, 2011), are proposed novel methods for compensator design for Generalized comb filter (GCF).

In (Molina Salgado, Jovanovic Dolecek & de la Rosa, 2015) is combined simplest corrector filter from (Jovanovic Dolecek & Fernande Vazquez, 2013) with the sharpening technique. In (Garcia & Jovanovic Dolecek, 2014) the corrector filters from (Jovanovic Dolecek & Fernandez Vazquez, 2013) are used in the recursive comb structure with the decimation factor which is power of two.

Different sharpening techniques are also used in multistage combs, and with corresponding compensators like in: (Gogi & Kulkarni, 2014), (Jayaprakasan & Madheswaran, 2013), (Jeong, Min & Kim, 2011), (Molnar, Pecotic & Vucic

2013), (Nikolic & Lutovac 2011), (Sukhpreet Singh & Panag, 2015), Jovanovic Dolecek, G. (2010), (Jovanovic Dolecek & Mitra, 2003), among others.

SOLUTIONS AND RECOMMENDATIONS

Generally, there is a trade-off between the quality of the improvement and the overall filter complexity. Knowing that comb filter is a simple multiplier less filter, the filters which improve comb magnitude characteristic in the pass band and folding bands, must also be multiplier less filters. The most promising methods are based on simple corrector filters. However, the existing corrector filters require high number of adders. Additionally, attenuation in all folding bands is not increased.

FUTURE RESEARCH DIRECTIONS

Future designs must be dedicated to the increase of the quality of magnitude improvement (low absolute value of pass band deviation and high folding band attenuation) and the decrease of complexity expressed in number of adders. Additionally, special interest will be in a low power and low area designs.

CONCLUSION

This article presents an overview of the methods for simultaneous decreasing of comb pass band droop and increasing alias rejection in the folding bands. Three main groups of methods are considered: Method based on sharpening, Methods based on simple corrector filters, and Methods that combine the methods for improvement of alias rejection and design of compensators that also include the methods combined with sharpening technique. Methods based on sharpening usually use the simplest sharpening polynomials. The compensators designed for comb filters cannot be directly used for the modified comb filters with an improved alias rejection. To this end, either the special methods are developed, or, new compensator parameters are defined.

KEY TERMS AND DEFINITIONS

Comb Corrector Filters: The simple filters used to correct pass band droop and to increase attenuation in the folding bands of the comb filter.

Comb Filter: The filter with all coefficients equal unity. Usually used as a decimation filter at first stage of decimation.

Comb Folding Bands: The frequency bands of the comb filter where aliasing occurs, and consequently must have high attenuation to attenuate aliasing.

Comb Order: The number of cascaded combs.

Pass Band Droop: Ideally, filter passes all frequencies without attenuation, in the pass band. Consequently, the magnitude response in the pass band must be equal to unity. If values of magnitude characteristic are less than unity in the pass band, then there is a pass band droop.

Pass Band Edge: The frequency which defines the pass band.

Sharpening: Technique used for simultaneous improvement of pass band and stop band of a linear phase finite impulse response filter. The technique uses a polynomial relationship between the amplitudes of the sharpened and the prototype filters, H_{sh} and H , respectively. The improvement in the pass-band, and the stop-band, of the prototype filter depends on the order of tangencies m and n of the polynomial relationship at $H=1$ or at $H=0$, respectively.

Worst Case Aliasing: The aliasing in the left edge of the first folding band.

Micro to Macro Social Connectedness Through Mobile Phone Engagement

Dominic Mentor

Columbia University, USA

INTRODUCTION

This chapter concentrates on the relationship between mobile phone use and social connectedness, emphasizing the various ways in which people use mobile communication as a means to cultivate and maintain social connectedness. The chapter explores the possible connection and relevance of social connectedness through mobile communication on a personal, group and macro level. Individuals are constantly shifting their roles and identities as they use their mobile phones; from personal to group, social to political, philanthropic, and civic participation as they traverse these different spaces. Included is a review of studies on how various mobile engagements, like mobile messaging, voice, video, social media and texting, is used by individuals. All of which has been repurposed within some formal and informal organizations for a variety of service objectives, including mobile learning with tacit or unintentional social connectedness embedded. The nurturing of social connectedness through mobile engagement is essential in people's lives as it reveals their ongoing and affective exchanges and experiences with a single friend, family member(s), an event, cause, artifact or a group. The cultivation of social connectedness can be used as a proxy for socio-emotional goals that can feed strong perceptions or real associations for people of all ages. The conceivable positive influence of social connectedness through multimedia or textual mobile messaging could be used to create a sense of affiliation and has a perceived usefulness for personal, civic, as well as academic and work life engagement.

BACKGROUND

The advent in 2001 and maturation standard of Multimedia Messaging Services (MMS) in 2002, extended text messaging to include, photos, animations (gifs), audio and /or video clips (MMS London, 2016). WAP Mobile communication services like Mixit, WhatsApp, and Kakao, broke the mobile messaging hold from mobile service providers, offering agnostic, and globally free access to one's contacts and Social Media Network Services (SMNS) communities. With features that encompasses voice notes, synchronous voice and video calling, to time set message deletion as with Snap Chat, all of which presents the ability to communicate with others and can serve as a powerful means to foster a sense of connectedness. Lam, (2012), and Ling (2015) as well as Cumiskey & Ling (2015) offers examples of how the mobile phone hosts a way for improving team attitude, playful identity, and social cohesion. While other multimodal messages are sent during a live or televised event, cultivating co-presence (Cui, 2016; Schroeder, 2010). The agnostic mobile messaging services have become the communication method of choice for building, as well as maintaining social connectedness, but also aids how individuals and groups traverse the different spaces of their lives.

Various definitions are touted for the concept of social connectedness that range from defining it as a sense of belonging, affiliations or associations (Chayko, 2007; Flomenbaum, 2008; Visser, Dadlani, van Bel, and Yarosh, 2010). Wei and Lo (2006) cites Teixeira (1992) as defining social connectedness as maintaining "interpersonal, community, and general social ties" (p. 62). While

the Jamieson report (2007) refers to social connectedness as how people come together, interact, and network, indicating electronic communication as an all-important factor in establishing and maintaining social connectedness. Berkman, Glass, Brissette, and Seeman (2000) stated that it is widely recognized that social relationships and affiliation have powerful effects on physical and mental health (p. 843), while Wyn & Cuervo et al., (2005) saw “the emerging technologies as enhancing social connectedness through the internet by means of web-blogs, social websites such as MySpace, and through mobile phone technologies via Short Message Systems (SMS)” (Martino, 2007, pp. 6-7). Chayko (2007) not only provides an overview of technologically generated communities, but also discusses the sociological implications of mobile technology as it pertains to a rise in personal availability and, more importantly, societal cohesion (p. 373).

Register and Herman views the concept of social connectedness as forming the basis for all human existence and similarly to the 2007 New Zealand report, indicates the phenomenon of connectedness that brings quality of life (Register & Herman, 2010, p.53). Whereas Lee, Draper and Lee sees social connectedness as “an attribute of the self that reflects cognitions of enduring interpersonal closeness with the social world” (2001). Other researchers asked, if social media or video calling is the new face-to-face (F2F) or if social connectedness can be derived from SMNS like Facebook or other online interactions and be linked to overall well-being (Grieve, Indian, Witteveen, Tolan, & Marrington, 2013; Lundy, & Drouin, 2016). Additionally, Krastel, Basselier, and Ramaprasad, (2015) found an important use and role of social features in online music sites, mostly accessed via mobile, as positively enabling social connectedness. Research studies from medical health to educational environments, and psychology to public health, all point to the importance and benefits of social connectedness (Berkman, Glass, Brissette, & Seeman 2000; Richards, 2016). The medical field point out faster

recovery rates from patients who have strong social connectedness ties (Cheung, Sedikides, & Wildschut, 2016), while numerous cases of educational benefits, from Henderson & Guy, 2016; Naismith, Lonsdale, Vavoula, & Sharples, 2004; Nolan, Hendricks, & Towell, 2016; Yoo, Miyamoto, & Ryff, 2016 have also proven as successful for enhancing teaming and success in an academic context (Lam, 2012; Walton & Cohen, 2011). The latter examples signify the many ways social connectedness can be defined, or leveraged in different contexts.

SOCIAL CONNECTEDNESS: MOBILE COMMERCE, GAMING, AND HEALTH

Issues, Controversies, Problems

Even though a unanimous definition for social connectedness does not necessarily exist, delineations centralize around a sense of belonging (Richards, 2016; Satici, Uysal, & Deniz, 2016) in a virtual, real or abstract sense with either people or an artifact. Controversially, virtual connectedness has become the new face to face. Especially from mobile phone video. Whereas mobile messaging, including SMS/texting, as well as social media updates through mobile has increased dramatically. According to Dag Kittlaus, co-creator of Siri, SMNS and mobile messaging dominated people’s attention and time on their phones (2016). The cross-platform mobile phone messaging services like Snapchat, WeChat, Facebook Messenger, Line, Kik, Twitter or Viber, has overtaken texting and phone calls, and have gained a prominent place in the social and communication spheres (Statistica, 2014). These apps have similar features of being able to share texts, images, video and other multimedia artifacts. SMNS like Facebook, Google Hangout, or the Chinese WeChat, Weibo, RenRen or QQ have all been optimized for mobile access. WeChat has also been described as more than a portal for performing mobile commercial transactions,

ordering taxi services, booking and delivering geo-targeted cinema tickets and coupons, processing person-to-person money transfers, and the ability to make utility payments or even accessing city services (Chan, 2015, Russell, 2015).

Whereas Hansen, Shneiderman, and Smith in 2011 contended email as the lifeblood of communication, professionals from medical, educational or commercial arenas, have drawn their attention to the rise in mobile messaging, accessing information via SMNS as well as other services via mobile phones (Lee & Phang, 2015; Moreno-Munoz, Bellido-Outeirino, Siano, & Gomez-Nieto, 2016; Wu, 2016). While the proclivity to mobile messaging is captured in the aforementioned studies, mobile communication can also nurture a connectedness or a sense of affiliation. Similarly, Chris Messina credited with initiating the creator of Twitter's hashtag (#), indicates that he "can find a community of 100,000 people online, whereas a couple of years ago I would have felt like I was the only one." There is also a daily practice of routine maintenance of connectedness (Al-Failakawi, 2006; Chilwa, 2008; Deng, 2013; Horwitz, 2014; Mbah & Ogbonna, 2012) through updates, 'snaps' or snap stories', postings, 'likes', or 'pokes', with SMNS and Mobile messaging services recording more than 60 billion messages a day as compared to 20 billion SMS text messages (Goode, 2016).

As with online social media, or mobile gaming, mobile phone communication provides the user with a virtual presence and on-the-go accessibility. Pokemon Go blends the virtual and physical realm through low level, but effective augmented reality. Players are tasked to walk to landmarks so as to earn points or get to Pokemons. The virtual presence holds true for one-on-one mobile gaming like Words with Friends, or multiplayer cross platform games like Spaceteam, Minecraft: Pocket Edition, Real Racing 3, or Super Stickman Golf. In short, the benefits of mobile phone engagement, offer a new, interpersonal means to stay involved with others (Crang, & Mohamad, 2016; Freeman, Bardzell, & Bardzell, 2016).

Various studies (Kim, 2016; Kim, Wang, & Oh, 2016; Longhurst, 2016) indicate that an individual's identity can be made up of self-regulated mobile interactions. In these diverse ways, mobile communication aids *agency* in managing social networks, and grants instant access to users' personal or organizational affiliations, while strengthening bonds and community spirit (Konok, Gigler, Bereczky & Miklósi, 2016). With mobile messaging apps and SMNS'es, the mobile phone contacts' list has grown and expanded beyond the initial family and friendship circle to include ephemeral contacts, businesses or organizations.

Organizational mobile engagement is situated within a different domain of practice from individual messaging, like businesses, public sector organizations or health and education entities. This type of engagement also includes mobile communication in many forms beyond organizational promotions. Numerous sectors of society have shown a growing interest in migrating mobile phone engagement habits to their or the clients' advantage. In the health sector, appointment reminders or sexual health texting (Rana, van den Berg, Lamy, & Beckwith, 2016; McIver, Dyda, McNulty, Knight, Wand, & Guy, 2016), or monitoring health (Berrouiguet, Baca-García, Brandt, Walter, & Courtet, 2016; Hannan, Brooten, Page, Galindo, & Torres, 2016) including smoking cessation with mobile gaming (DeLaughter, Sadasivam, Kamberi, English, Seward, Chan, Volkman, Amante & Houston, 2016; Jamalian, Mezei, Levitan, Garber, Hammer, & Kinzer, 2012) have been researched. The medical health focus of the literature covers the same themes many an organization or person can benefit from as a whole. With reminders for appointments, taking medication, or offering paramedical support, discreet sexual health information services, shows the individual's ability to host connections to multiple environments. Although the aforementioned studies are different in terms of their purpose and focus, it is also the size of the organization, private or the number of participants involved that

actuate the basic set up, structure and power of the mobile engagement processes. These lessons are also relevant for any migration of use from personal messaging to institutional, promotional or wide scale mobile macro engagement.

From Micro to Macro Mobile Communication with a Cause

Macro level mobile engagement range from political campaigns, emergency responses or the revolutionary moments in northern Africa during the Spring of 2011. With continuous innovation, and creative repurposing of mobile apps and tools, a connectedness to socio-political issues abound around the globe. From the 2012 French election, 2016 USA presidential campaign to Obama's first election campaign when he announced his VP candidate via mobile communication (Baumgartner, Mackay, Morris, Otenyo, Powell, Smith, & Waite, 2010; Kenski, & Conway, 2016; Wells, Van Thomme, Maurer, Hanna, Pevehouse, Shah, & Bucy, 2016; West, 2012), are all examples of macro level mobile engagement. According to Baumgartner, et al (2010) and West (2012), Obama's campaign made use of texting and SMSN to identify and communicate with supporters, but also to raise money and coordinate virtual gatherings simultaneously across the country. According to West and the Mobile Economy Project (ibid.), mobile phones could expand mobilizing opportunities and increase citizen participation in civic issues, but could also cultivate government accountability.

In the words of the researcher John Donner "mobile phones accelerate urban metabolism" (2006), and in the case of the Tunisian and Egyptian revolutions, the use of mobile phones heightened the demonstrators' ability to coordinate protests as well as facilitate and disseminate the flow of information (Potts, 2011). With the rise of mobile phones, people are able to micro-coordinate (Ling, 2008, Mentor, 2014) more than just rendezvous' points or revolutions, but their daily activities from ordering food, car services,

mobile payments, or philanthropic support of a cause. Some of these affordances were re-modeled as a powerful macro-coordinating tool during various campaigns ranging from Black Lives Matter protests to elections. Now, with relative ease, a whole country's population can connect and mobilize to rally around a single agenda. Moving from one-to-one communication models, to one-to-many and many-to-many communication connectedness, like the mass protests and toppling of government examples mentioned earlier, there has been powerful utility in many modern day scenarios. For example, monitoring for free and fair elections in a crowdsourcing manner in any country with mobile phone infrastructure; from Kenya (Jeffery, 2011) to hopefully the USA.

Other examples of crowdsourcing through mobile phones are fast being adopted all around the world from crime reporting to live video broadcasts via mobile phone. Some examples include: South Africa's Corrupt Watch (2012), Kenya's Hatari Crowdmapping of various kinds of crime, mobile technology for crowdsourced agricultural development (Baumüller, 2013), Atlanta's MapATL for crime statistics, and New York City's DOT report a street maintenance reporting tool. Live mobile broadcast featured prominently in the global political arena in 2016 from legislative sit-ins in the USA protesting about gun violence (Folkenfalk, 2016; Peterson and Andrews, 2016) to the Turkish president debunking a coup and calling on the Turkish people to take to the streets in protest (Sherr, 2016). Live video recording and broadcasting with tools like Meerkat or Periscope, are used to document people's lives, documenting police brutality, a live show or kayaking down the Chicago river. One can but only hope that the continued rise of live mobile recordings and broadcasting will become part of police training, protocol or naturally evoke a sense of a panopticon in those police personnel who need it. These efforts rally the cognitive surplus (Shirky, 2010) of communities and unleashes the power of ordinary people by converting the mobile phone from a one-on-one communication

device to a one-to-many mass media tool. Issues of corruption, collating ideas and having people's voices heard by mobile means, impacts mobile civic engagement. People can report incidents which in turn builds consensus and connectedness to and with a cause. The new and unique ways that a previously private device can now be employed and affect change, is inspirational and speaks to the empowerment of people converted to participative citizens.

Problematically, many organizations and government entities have still not wholly embraced the wide spread adoption and practice of mobile service delivery. While bars and businesses, many educational institutions, live events or television shows invite you to interact with them via social media with photos or tweets, government departments are still neglecting to offer mobile friendly services or are still playing catch up in offering mobile first service designs.

SOLUTIONS AND RECOMMENDATIONS

There is a strong need for government agencies to partner with businesses, higher education and/or software companies and software engineers. This would cater for engaging with any of the aforementioned stakeholders' constituents, but also contribute to and promote social accountability. Many examples of multi-disciplinary efforts abound, with three examples to mention (a) a project that leveraged technology graduate students in New York City to build solutions or improvements in partnership with the New York Mayor's Office of Adult Education (Mentor and Murdoch, 2011), (b) The World Conference on E-Learning in Corporate, Government, Healthcare, and Higher Education (AACE, 2015) and the Obama administration's successful appeals to have software technology companies and individuals fix and improve the Healthcare web portal (Dawes, Vidasova, & Parkhimovich, 2016).

Given the mobile phone as the go-to, in-hand device for all of the aforementioned, this rapid movement has also informed a mobile first design framework (Van Esselstuyt, 2015). There certainly has been an increase in the adoption and adjustment to mobile first designs for websites, however, the need is still massive for a mobile first e-learning design approach (Curinga & Svaranos, 2016) as well as mobile first usability studies. The latter could aid and perhaps speed up the development of government and other organizational electronic engagement, which in turn could lead to better service offerings via mobile devices and improvements to quality of life offerings.

FUTURE RESEARCH DIRECTIONS

This chapter looked at the concept of social connectedness and the ways it may have been revealed in the studies referenced in this chapter. The categorization of the different mobile communication can be categorized into three groups of pairs, groups and macro levels. That categorization can be used to assist contextualizing the scope of micro or macro mobile communication and examine how the mobile engagement projects can be designed and delivered in different contexts.

The literature reviewed exemplifies that there is quantitative value in the number of mobile engagements. However, the socio-emotional aspects are prevalent, but cannot necessarily be quantified. What is lacking is a multifaceted mixed methods approach and analysis that looks at reported perceptions of socio-emotional value of social connectedness. Additionally, how trust circles have expanded on a previously considered private device via SMNS and if quality of life was truly impacted beyond just civic service delivery, but also through socio-emotional elements. Further research into the deeper causal relationships that exists between organizations and the individual participant is needed. Organizational and macro level mobile engagement needs to be interrogated

beyond commercial interest, but also how perceptions of social connectedness possible offer intangible support. Additionally, a delphi method could help establish a guide or definition for the concept of social connectedness which could offer further research direction with clarity, especially with the multitude of mobile devices and tools from which connectedness could be cultivated and maintained.

With the proliferation of mobile devices, apps and repurposing of handheld device tools, as well as the ability to collect big data through mobile engagement, there is a continued need for big data research studies. The quantitative approach could delve into granular or big data per user, group or cause, while the qualitative approach could offer insights via semi-structured individual or group interviews, focus groups, using a snowball method, or grounded theory. While quantitative analysis could be applied to all mobile communication or activity logs, short or long form surveys could be conducted prior to or after interviews to aid triangulation or crystallization of data. Mobile surveys could aid research input and design, if it takes a mobile first design and delivery approach, which could leverage a conditional method of posing questions, one at a time, and providing a question based on the previous response. Conditional surveys taken on a mobile device provides manageable bite size questions and response fields and could aid a deeper digging into specific aspects of the research area that needs to be investigated. However, completing a text survey could be influenced by the form factors and element interactivity of the mobile devices, due to physical constraints. The multitude of considerations for the varying form factors found in different geographic locations however could be overcome by a web responsive mobile first design.

As mobile digital geographies grow, become more complex and condensed at the same time, through SMNS and other mobile device activity, data visualization could be leveraged to offer snapshots of moments in time, or offer insights and analysis into social networks in a far quicker

manner than longitudinal studies. Another pictorial method that could be employed in conjunction with or separate from data visualization would be concepts maps for future mobile social connectedness research designs.

Additionally, Özçınar's 2016's research method of visualizing the evolution of mobile learning research through a co-citation analysis paradigm could be used as means to conduct and map research on social connectedness through users' mobile device use. However, capturing the research of human interaction through mobile computing systems, would not address gaps or needs of users. There would be a need to add to the co-citation approach with a specific focus on one element. Be it individual users, groups, causes or even specific devices, countries or regions within a country or the world. By zoning in on a specific focus, would offer data integrity to the investigations of mobile social interactions. Different countries have a multitude of service providers, competitive markets and costs that impact the use of mobile devices. Thus, research framing or foci will differ by country, and in the case of the USA and many countries, even by States or regions. Other demographic or genogram aspects could also be investigated to offer cross-sectional or comparative studies where factors such as access to mobile devices, usage according to age, family make-up, birth order or gender. In terms of information science, further research could focus on particular devices or a device, activity trends, or how social connectedness can be leveraged for education or exploited for mobile commerce.

CONCLUSION

Many more organizations have and want to dive into the use of mobile device engagement, (Chavin, Ginwala, & Spear, 2012; Muench, Stolk-Cooke, Van Morgenstern, Kuerbis, & Markle, 2014; Nielsen & Webb, 2011; Quin, 2013; West, 2014), but lack the theoretical and/or technical expertise. The size and shape of these organizations vary

and that bears upon the context and operational process of each organization's mobile intervention. The studies reviewed in this chapter show how mobile messaging increases social connectedness and improves people's quality of life. It must be noted that although life benefits and community affordances are possible because one's phone is always available; feelings of connectedness are not caused by the mobile phone itself. Fostering a sense of community is dependent on the reciprocity of communication initiated via the mobile phone, be it by voice calling, messaging or SMNS activity. Many of the processes and lessons learned from the literature reviewed, be it from mobile messaging research conducted within the health care settings or the political arena, could be applied to the workplace, educational, local city or federal governmental settings to offer socio-emotional support or services that could aid academic success and social well-being.

KEY TERMS AND DEFINITIONS

Co-Presence: The practice of people engaging in real-time face-to-face social activities and being engrossed in the here and now of that social activity, but also being virtually present and via texting or mobile messaging with dual occupation of real and virtual space.

Connected Presence: Unconstrained connections from time and place, refers to people situated in a different physical location, but splitting their attention and connecting via virtual means with another location or person located elsewhere.

Mobile Crowdsourcing: Mobile crowdsourcing describes the collation of a large group of people's views and/or observations. These crowdsourcing activities are processed on mobile phones or other handheld mobile devices.

Mobile Learning: Also known as mLearning refers to creating, leveraging or designing learning opportunities via portable technologies from and/or for interpersonal and organizational mobile communication.

Mobile Messaging: Mobile messaging typically from a mobile phone or mobile device. Examples include SMS texting, Multimedia Message Service (MMS) to a host of wireless access protocol (WAP) mobile messaging services like WhatsApp, WeChat, Kakao, Kik, Line, etc. The latter being device agnostic, meaning they can be installed and used on many different types of mobile phone platforms.

Mobile Social Media: Social communication and networking where affiliated individuals with dis/similar interests converse and connect virtually and/or in-person with one another through their mobile phone, handheld and/or tablet device.

Social Connectedness: Concept often been used to characterize degrees of interpersonal trust, attachment security, social competency, and a sense of belonging, online and in real world.

Socio-Emotional: The concept of socio-emotional aspects refers to a person initiating, cultivating and responding to others, to form relationships with other people in their lives such as parents, relatives and friends. These socio-emotional aspects can be ephemeral or long-standing, when it comes to interactions with people. Typically with familiar, but not excluding unfamiliar people. It can span the spectrum of how people interact with others to how they manage communication or cope with adversity, stress, establish positive relationship and the capacity to develop relationships with peers, often times through communication.

Mobile Applications for Automatic Object Recognition

INTRODUCTION

In recent years, the technological improvements of mobile devices in terms of computational capacity, embedded sensors, natural interaction and high-speed connection are enabling an ever-increasing number of designers to develop advanced mobile applications to be used in everyday life. Among these, the vision based applications for the Automatic Object Recognition (AOR) play a key role since enable users to interact with the world around them in innovative way that makes more productive and profitable their entertainment, learning and working activities. Within the introduced topic, objects can be physical entities of any type, from small sized objects (e.g., paintings, statues) up to medium sized objects (e.g., road signs, vehicles) or large sized objects (e.g., airplanes, buildings). The real step forward in moving the AOR from the common Computer Vision (CV) paradigm to that of the Mobile Vision (MV) is the ability to perform, with a mobile device, the recognition and classification of objects both in pervasive way (i.e., anywhere, anytime) and in indoor as well as outdoor environments. Up to about ten years ago, the only way to recognize an object of the

real world acquired by an RGB mobile camera in outdoor environments was the adoption of visual expedients (e.g., markers, barcodes) which, once recognized, contained all the required information of the target object. Although it is still an open issue, the recent advances in image quality, image feature extraction and image classifiers make possible the automatic recognition of an ever-increasing number of objects. Nowadays, there are many AOR applications that support a wide range of popular fields (e.g., culture, tourism, food). In addition, recently, an ever-increasing number of AOR applications aimed in supporting professional fields (e.g., forensic, architectural, engineering, medical) have been developed. The proposed chapter is divided into four sections. The first one, Background, introduces a taxonomy of the current mobile applications and explores the most recent works in AOR mobile applications highlighting crucial aspects of the object recognition algorithms, including the feature extraction processes and the implemented classifiers. The second one, MV Development Technologies, provides an overview of the current frameworks used to support mobile AOR applications. The third one, Future Research Trends, briefly discusses the

DOI: 10.4018/978-1-5225-2255-3.ch538

aims of the next generation of AOR applications. Finally, the last one, Conclusion, summarizes what has been reported in the present chapter.

BACKGROUND

In the last decade, mobile devices have had ongoing and growing technological advances. Currently these devices, even those of low cost, have a set of hardware features that make them comparable with a wide range of desktop processing units. In fact, these mobile devices, with particular reference to those of the latest generation, present a set of significant improvements, including:

- **Multi-Core Processor (MCP):** A single processor that contains several cores. This technology typical of common processing units (e.g., workstations, servers) allows mobile devices to rapidly process a large amount of data also improving the performance of running multiple applications.
- **Advanced Storage Capacity (ASC):** A large amount of internal memory and the possibility to adopt external memories (e.g., compact flash, memory stick). This technology allows mobile devices to support both complex data and bulky applications.
- **Mobile Sensing (MS):** The set of sensors embedded in a mobile device. This technology allows mobile devices to be equipped with a wide range of sensors, including: Red-Green-Blue (RGB) sensor (i.e., image camera), Global Position System (GPS) receiver (i.e., localization system), accelerometer sensor (i.e., proper acceleration “g-force”), gyroscope sensor (i.e., orientation system) and others. These sensors are used to acquire any type of information from both the external world (e.g., images, temperature, pressure) and user’s behavior (e.g., speed, locations, actions).
- **Natural User Interfaces (NUIs):** The set of natural interfaces to favor the Human-Computer Interaction (HCI) between users

Figure 1. A taxonomy of mobile applications

and mobile devices. This technology allows users to adopt human-oriented interfaces (e.g., speech recognition, touch-screen interaction) to manage data and devices.

- **Fast Internet Connections (FICs):** The set of information and communication technologies (ICTs) that allow devices to access to any type of resource, including: World Wide Web (WWW), cloud computing, dedicated networks and others.

In contrast to the common processing units (e.g., laptops, desktops), the mobile devices are versatile and pervasive. Moreover, they can be suitably used in indoor and outdoor environments. The introduced aspects have shifted the role of the mobile devices far beyond their original aim. Today, these latter are considered real tools to support each and every activity of the human life thus promoting an ever-increasing development of mobile applications in any kind of context including entertainment and tourism as well as learning and working. In Figure 1 a taxonomy of the current mobile applications is reported. Although more classes of the taxonomy can characterize any application, usually one of them can be considered the main one, that is, the class that more than others defines aims and scope of the application itself. Among the mobile applications, those based on vision play a key role since they allow users to expand one of their senses: the

sight. In fact, nowadays, the AOR applications support many critical tasks, including: forensic investigations, interior design and visual disabilities. Finally, it should be noted that currently the term mobile device covers a wide range of tools from the common smartphones up to the handheld tablets or intelligent glasses. In the next subsection, a selected set of AOR mobile applications is provided. For each of them two main aspects are highlighted: feature extraction process and the implemented classifier.

AOR Mobile Applications

The RGB camera is the most common sensor equipped within the current mobile devices. Its typical standard resolution for the acquisition of static photos is 12 megapixels (MP), while the acquisition of video is usually performed in 1080p (i.e., Full High Definition, FHD, defined as 1080 x 1920 pixels) with 30 frames per second (fps). Moreover, these cameras are often controlled by embedded software able to optimize their main features, including: image stabilization, sensor focus and image color balance. All these characteristics have a huge importance since each vision based mobile application works by processing one or more photos, otherwise a video in on-line or off-line mode. In any case, regardless of a specific task, the pipeline of an AOR mobile application can be generalized as shown in Figure 2.

Figure 2. Typical architecture of an AOR mobile application

In general, the first step of an AOR mobile application is the definition of the database containing a template representation (i.e., feature descriptors) of each object to be recognized. The construction of the database is usually performed in monitored environment where all the technical aspects (e.g., lighting, contrast, resolution) are carefully treated. The database can be made available to the mobile application locally (i.e. embedded within the application) or remotely (e.g., via server or cloud). When the mobile device acquires a set of photos or a video from the real world containing the target objects, a description of them (i.e., features descriptors) is extracted. The last step of an AOR mobile application is the comparison (i.e., feature matching) between these descriptions and the ones previously stored within the database to detect the correct object and provide the linked information to the user. In Figure 3 an example of AOR mobile application for the recognition of paintings is reported. In particular, the Figure 3 highlights three main steps of the application running: scanning of a region of interest (left), recognition of the painting (middle) and, finally, the feedback provided by the application to the user (right).

A first remarkable AOR mobile application is presented in Saeed et al. (2013), where the authors describe a system to help blind and visually impaired people to better understand the environments in which they live and work thus improv-

ing the quality of their life. The proposed system has different strengths, including: high accuracy, speed, portability and low cost. The AOR mobile application designed by the authors adopts ORB as local feature detector and descriptor. They claim that the main reason behind this choice is that ORB is able to compute and match sets of feature descriptors very efficiently. Since the real-time performance is a mandatory requirement of their application, the authors have preferred ORB to other local feature detectors and descriptors (e.g., SIFT, SURF) which are more robust to viewing condition changes. The classifier of the proposed system has been implemented with three different variations. In the first one, the classifier adopts a similarity matching measure based on Hamming distance. In this context, the Hamming distance can be considered as the measure able to quantify the similarity of two key points in terms of shape and color properties. In the second one, the classifier adopts an outlier removal technique based on Nearest Neighbor Ratio. This technique tends to consider as inliers those keypoints (of a live image) whose Hamming distance from a reference keypoint (of a database image) is less with respect to a fixed threshold. However, regardless a specific classifier, the AOR mobile application described by the authors presents high levels of robustness and performance.

Another interesting and funny AOR mobile application is reported in Kawano et al. (2013),

Figure 3. An example of AOR mobile application for the recognition of paintings

where the authors detail a food recognition system able both to estimate calories and nutritious of foods and to record the user's eating habits. Also in this case, the system proposed by the authors has different strengths, including: high accuracy and speed. The authors have spent a large amount of time to study a suitable algorithm able to extract in real-time a set of key features from the target objects. Finally, they have chosen a combination between color histogram and Bag-of-SURF as feature detector and descriptor. In particular, for the extraction of a first set of keypoints the authors subdivide the target image into 9 blocks (i.e., 3 x 3 blocks) and extract a 64-bin RGB color histogram from each of them. Another set of keypoints is extracted from the image by using a SURF variation of the Bag-of-Words. This last is a technique initially developed to support the natural language processing where a document (i.e., a set of sentences) can be represented by a histogram (i.e., occurrences) of its words disregarding the grammar. In CV this algorithm has been expanded with the opportunity to consider the keyfeatures of an image instead of the words of a document. The authors have adopt a linear Support Vector Machine (SVM) as core of the classifier. In general, a linear SVM is an algorithm able to separate two sets of objects into their respective groups. In the context proposed by the authors, each SVM classifier is able to recognize a specific food category. Since they have tested the AOR application with 50 food categories, they have trained it with 50 linear SVM classifiers.

A very interesting and practical AOR mobile application is described in Chen et al. (2015), where the authors present a multi-purpose, continuous, real-time object recognition system. The application proposed by the authors presents a wide range of advanced features: it captures full-motion video, locates objects of interest, recognizes and labels them, and tracks them from frame to frame for the user. The authors claim that their algorithms for the object recognition entail significant computation, for this reason their system runs them on server machines. During the development,

the authors have taken care of several technical details to support the effectiveness and robustness of the application. Among these, an active cache of video frames has been implemented to overcome possible latency issues due to the communication between server and mobile device. In this project, the authors have mainly adopted SIFT and SURF as feature detectors and descriptors, while they have mainly used SVM as classifier. The proposed AOR mobile application has been tested on a wide set of objects (e.g., road signs) concerning different scenarios. The results have shown that the application achieves high precision and accuracy, moreover, its architecture is able to save bandwidth and resources. This system can be considered a step forward over the current state-of-the-art.

The authors of the work reported in Hong et al. (2012) present an AOR mobile application for the recognition of flowers. This work is of particular interest since the target objects are usually placed within natural environments whose background is affected by several critical aspects (e.g., light, surrounding objects) that make the feature extraction process from the foreground a hard task. Their system is based on a client-server architecture, where the client (e.g., smartphone) acquires flower images and sends them to a remote server that, after the processing step, provides to the user a feedback concerning their classification. The system proposed by the authors adopts a complex feature extraction process based on searching for the

contour of flowers by using color and edge information. The features extracted by means of these latter are compared with the images stored into the database by using a classifier based on color clustering and distance histogram matching. Like the previous selected works, also in this case the authors have obtained remarkable results. The application could be also customized for the recognition of other kinds of objects.

A different work is discussed in Jung (2012), where the author explains an AOR mobile application whose classification approach has been

specifically designed to be trained and recognized by a mobile device. The system has been developed with a dual purpose. The first one regards the opportunity to recognize a three-dimensional object on a two-dimensional photo, even when the object is shown from different perspectives and presents different shadows and reflections. The second one concerns the opportunity to perform the training phase, related to the introduction of new objects within the database, by using the mobile device. The proposed AOR application adopts a complex feature extraction process. A first part of the feature vector is composed by color, edge activity and frequency-based features which are obtained from a statistical analysis of local image properties. This makes the features robust against image variations, but also makes them blind towards the geometrical shapes of the objects themselves. To compensate this aspect, the rest of the feature vector is composed by interest point features that are computed by using the SURF algorithm. Also in this application, the author has used SVM as classifier thus obtaining excellent results.

Analyzing the literature, in the last decade, other considerable systems that share technical aspects with the previously discussed AOR mobile applications have been developed. In Hua et al. (2014), for example, the authors have designed an interesting recognition system that can work both with images and with arbitrary entities. While, the work reported in Ling et al. (2011) presents a robust, portable and expandable system for the automatic recognition of traffic signs. The authors of the work described in Quack et al. (2008) show a sophisticated system that combines the concepts of object recognition and Internet of Things (IoT). They present an AOR application that allows to request information on physical objects by taking a picture of them. Finally, the work detailed in Kumar et al. (2012) introduces a novel multi-frame object detection application for the mobile platform that is capable of object localization. The significance of their method is

its ability to bring evidence from minor changes in views to improve object detection.

A last work, Aletto et al. (2016), is now introduced to illustrate the generalization of the term mobile device. In this latter the authors propose to adopt the first person prospective and a wearable device to support a tourist during the exploration of a site. Their system is designed to retrieve architectural details of historical buildings and to provide feedback and information to the users. The main idea behind this project is that, in an unconstrained outdoor tour, a user may not be able to autonomously identify all the relevant details in the site. So having a smart embedded guide that sees what a user sees and can provide precise and contextual information when asked to could result in a more enjoyable and complete experience. The object recognition application proposed by the users is composed by a wearable board, a glass-mounted camera, a wireless audio output device and the visitor's mobile device. Using the latter as interface, the user can ask the system to acquire a frame from the wearable camera, process it, and retrieve all the details present in the scene. The user can then see a visual representation of the output on the device screen, where tapping each detail provides audio information regarding the selected detail. The current technology improvements are allowing to obtain devices (e.g., Google Glass) which integrate all-in-one the described interfaces.

With the aim to provide an overview of the just reported keypoint detectors and descriptors, Table 1 summarizes some basic information about SIFT, SURF and ORB (Isik et al. (2015)).

Analyzing the reported works, it is possible to observe the widespread usage of the SVM classifier. This fact is due to several features which are reported within the Table 2.

MV DEVELOPMENT TECHNOLOGIES

All the AOR mobile applications reported in the previous section have been developed by using

Table 1. Keypoint detectors and descriptors

Algorithm	Main Information
SIFT	• The Scale-Invariant Feature Transform (SIFT) is a keypoint detector and descriptor. It consists of four main stages (Lowe (2004)): ◦ Scale-Space Extrema Detection: The algorithm searches over all scales and image locations. It is implemented efficiently by using a difference-of-Gaussian function to identify potential interest points that are invariant to scale and orientation; ◦ Keypoint Localization: At each candidate location, a detailed model is fit to determine location and scale. Keypoints are selected based on measures of their stability; ◦ Orientation Assignment: One or more orientations are assigned to each keypoint location based on local image gradient directions. All future operations are performed on image data that has been transformed relative to the assigned orientation, scale, and location for each feature, thereby providing invariance to these transformations; ◦ Keypoint Descriptor: The local image gradients are measured at the selected scale in the region around each keypoint. These are transformed into a representation that allows for significant levels of local shape distortion and change in illumination.
SURF	• The Speeded Up Robust Features (SURF) is a keypoint detector and descriptor. Its pipeline is similar to that of SIFT, but includes some significant differences aimed to make SURF faster, in particular (Bay et al. (2008)): ◦ The algorithm computes the keypoints by using the Fast-Hessian Detector that bases on an approximation of the Hessian matrix for a given image point; ◦ The responses of Haar wavelets are used for orientation assignment, before the keypoint descriptor is formed from the wavelet responses in a certain surrounding of the keypoint.
ORB	• The Oriented FAST and Rotated BRIEF (ORB) is a keypoint detector and descriptor. It has been developed by the composition of FAST keypoint detector and BRIEF keypoint descriptor, where (Rublee et al. (2011)): ◦ Features from Accelerated Segment Test (FAST) is a corner detection algorithm whose main strength is the computational efficiency, while its main weakness is the inability to produce scale-invariant keypoints. However, due to its high speed performance FAST is very suitable for real-time image and video processing; ◦ Binary Robust Independent Elementary Features (BRIEF) is a feature point description algorithm that can be combined with arbitrary detectors. The main weakness of BRIEF is that it can not manage wide rotations of the feature points. • In a first step, ORB uses FAST to quickly find the keypoints of an image and adds an additional component to FAST to manage their scale. In a second step, ORB uses BRIEF to accurately describe these keypoints and adds an additional component to BRIEF to manage their rotation.

one or more computer vision frameworks. These last are useful tools that include a wide range of basic algorithms which can support the most common aspects of the implementation of any application, including: feature extraction, client-

server communication, classification process and others. Since an AOR mobile application can be developed both in embedded and in client-server mode, each framework can be potentially used with any kind of mobile device (e.g., Android,

Table 2. SVM classifier

Classifier	Main Information
SVM	• The Support Vector Machine (SVM) can be considered one of the most effective classifiers to support applications in real contexts. This is due to several technical features which are briefly reported below (Tong et al. (2002)): ◦ The basic form of the SVM is based on the concept that two classes of objects can be suitably separated by a linear function. This simple and effective method results robust enough to be used in a wide range of practical cases since in these latter it is quite easy to find such sets of discriminative features; ◦ Unlike other popular classifiers (e.g., HMMs, NNs) the SVM can be easily implemented in supervised or unsupervised mode according to the requirements of the specific application; ◦ The linear SVM can be extended to a non-linear classifier by expanding the plane of the solutions into a feature space by using a set of non-linear basic functions. These latter can be computed by means of a kernel representation whose solution is written as a weighted sum of simpler functions. In this way, the SVM can be used to classify more than two classes maintaining, at the same time, all the advantages of the linear case; ◦ In the last ten years, an interesting new trend has regarded the implementation of the classifiers by means of the Neural Trees (NTs), which have the same benefits of the SVM based classifiers but can be also used in complex environments (Foresti et al. (2004a), Foresti et al. (2004b)).

Table 3. Computer vision framework

Framework	Main Features	Notes
OpenCV	- It is composed by the following main modules: Core: It includes core functionalities such as the management of the data structures and macros; Image Processing: It includes image filtering, geometric image transformation, histograms; Video Analysis: It includes motion analysis, background analysis, object tracking; Features Framework: It includes feature detectors, feature extractors, feature descriptors, feature matchers, object categorization; Machine Learning: It includes statistical models, SVM, decision trees, boosting, neural networks.	- Current version 3.1 under a BSD license. - Written in optimized C/C++. - Desktop OS: - Windows, Linux, Android, MacOS; - FreeBSD, OpenBSD. - Mobile OS: - Android, Maemo, iOS. - Supported Modules: - CUDA, OpenCL. - Link: http://opencv.org/
BoofCV	- It is composed by the following main modules: Image Processing: It includes binary images, color space, image filters, image derivate; Feature: It includes associate interest points, edge detector, dense optical flow, fitting ellipses; Segmentation: Color segmentation, super-pixels, thresholding, watershed with seeds; Structure from Motion: Perspective-n-point, multi-view scene reconstruction.	- Current version 0.23 under an Apache 2.0 license. - Written in optimized Java. - Supported Modules: - Dedicated Kinect module; - Dedicated Android module; - Link: http://boofcv.org/
SimpleCV	- It is composed by the following main modules: Features Package: It includes feature extractors, morphology features, image filters, blob filters; Machine Learning Package: It includes SVM classifier, confusion matrix, KNN classifier, shape context classifier, temporal color tracker; Segmentation Package: It includes MOG segmentation, color and running segmentation; Tracking Package: It includes LK tracker, CAM shift tracker, MF tracker, SURF tracker.	- Current version 1.3 under a BSD license. - Written in optimized Python. - Desktop OS: - Windows, Linux, MacOS. - Mobile OS: - Android. - Required Modules: - OpenCV. - Link: http://simplecv.org/
EmguCV	- One of the main feature of the framework is the .NET wrapper for the OpenCV image processing thus including all its libraries, such as: - Core functionalities; - Image Processing; - High-Level GUI and Media I/O; - Video Analysis; - Camera Calibration and 3D Reconstruction.	- Current version 3.1.0 under dual license that includes also GNU GPL v3. - Desktop OS: - Windows, Linux, MacOS. - Mobile OS: - Android, Windows Phone, iOS - Wrapper Module for OpenCV. - Link: http://www.emgu.com/

The table shows only a little portion of the features of each framework (follow the link for the whole set).

iOS, Windows Phone). For this reason, Table 3 summarizes some main information of some of the most popular computer vision frameworks regardless of a specific Operative System (OS) mounted on a mobile device.

FUTURE RESEARCH DIRECTIONS

As presented in the previous section, in literature exists many significant mobile applications able to automatically recognize objects on a scene.

Mainly, they are based on robust recognition algorithms that include both feature extraction processes and classifiers. The current state-of-the-art of these algorithms has been designed by considering as input both images and video frames at standard resolution. Nevertheless, the last generation of mobile devices are equipped with more sophisticated image sensors able to capture static images with a higher resolution (e.g., 16MP) as well as videos in Ultra High-Definition (i.e., 3840 x 2160 pixels with 30/60 frame per second) or higher. This breakthrough in image and video

resolution will allow feature extraction algorithms to better distinguish objects into the scene. Moreover, also objects placed at long distance will be processed in more accurate way. It is worth noting that high resolution frames include a large number of pixels compared to those at a standard definition, thus are required high computational costs to process each of them. However, it should not be a significant issue since, usually, the evolution of the camera sensors follow the evolution of the processors mounted on mobile devices.

Another important feature that should be investigated in future researches regards the use of the IR cameras. These latter are particular image sensors through which the depth maps of persons and objects are built. The maps of these elements show the distance between them and the camera thus making the recognition process simpler with respect to the traditional approaches based on RGB cameras. One of the first mobile devices in this direction is Tango, a Google's project that adopts an advanced tablet equipped with an RGB-IR camera and combines 3D motion tracking with depth sensing to provide the tablet with the ability to know where it is and how it moves through space (source: <https://www.google.com/atap/project-tango/>). Finally, a last future proposal should be the analysis of the innovative cloud infrastructures (e.g., clustering networks) which can support both complex recognition applications and computational costs.

CONCLUSION

In this contribution, a selection of some of the most important AOR mobile applications has been presented. For each of them the feature extraction process and the classifier have been highlighted. The contribution has also reported some main features of some of the most popular computer vision frameworks used to support the develop-

ment of the mobile applications. Initially, the contribution has also provided a possible taxonomy of the mobile applications to point out the large amount of tasks that are currently supported by these applications. A brief analysis of the future research directions concludes the chapter. In this latter, the role of the next generation of mobile technologies is highlighted.

KEY TERMS AND DEFINITIONS

Computer Vision (CV): The field of the computer science that deals with the analysis and understanding of images and videos. This field covers a wide range of practical and theoretical topics, including: image and video acquisition, feature extraction, image and video understanding, feature representation and feature matching. This field is also closely linked to a huge amount of scientific disciplines, including: artificial intelligence, machine learning and pattern recognition.

Feature Extraction (FE): The process for the extraction and description of salient points from images and videos. Any image, or frame of a video, can be represented by a set of keypoints (i.e., features) whose aim is to highlight and synthesize shapes, objects and properties contained within them. These keypoints are extracted from an image, by a detector algorithm, and, subsequently, they are exhaustively described, by a descriptor algorithm.

Feature Matching (FM): The process for the comparison of two sets of keypoints coming from two different images or video frames. The process compares the description of each keypoint of the first image (or frame) with each keypoint of the second image (or frame). A rank algorithm establishes a list of the best matching between them. This process is used to check the bi-univocal correspondence between the keypoints of two similar or overlapped images (or frames).

Global Position System (GPS): A radio navigation system that provides accurate positional data of an object equipped with a GPS receiver. The positional data is referred to the surface of the earth and include latitude, longitude and altitude along with the time. This basic information can be processed by the receiver to derive other dynamic data, such as: speed and acceleration. The working of the GPS system is due to a network of satellites deployed in the space that continually emit a measurable signal.

Human-Computer Interaction (HCI): The field of the computer science that deals with the interaction between users and computers. The aim of the HCI is the definition of interactive interfaces by which to guide any system (desktop or mobile) in respect to the usability principles.

IR Camera (IR-Cam): A camera equipped with an infrared (IR) technology (i.e., IR projector and IR sensor) through which the depth maps of persons and objects are built. The maps of these elements show the distance between them and the camera thus making the recognition process simpler with respect to the traditional approaches based on RGB cameras.

Mobile Vision (MV): The field of the computer science that deals with the analysis and understanding of images and videos focused on mobile devices (e.g., smartphones, tablets).

Natural User Interface (NUI): The field of the computer science that deals with the human-oriented interfaces. The term NUI highlights that these interfaces have to be invisible to the users. The NUI interfaces are designed to detect the natural actions of the human beings (e.g., hand movements, body poses, body gestures) and use them to interact with any kind of system.

Object Classification (OC): The field of the computer science that deals with the classification of objects. The classification is supported by a specific algorithm named classifier which can be implemented by using different theoretic principles, including: machine learning, statistical approaches, mathematical approaches, geometrical approaches and exhaustive computations.

Object Recognition (OR): The field of the computer science that deals with the recognition of objects. It consists of a set of algorithms, including: feature extraction, feature matching and object classification. OR regards both images and video frames.

RGB Camera (RGB-Cam): A camera equipped with a standard CMOS sensor through which the colored images of persons and objects are acquired. The acquisition of static photos is usually expressed in megapixels (e.g., 12MP, 16MP) that define the amount of pixels (i.e., length x height) that compose a photo. While, the acquisition of videos is usually expressed with explicative terms such as Full HD (i.e., 1080 x 1920 pixels with 30 frame per second) or Ultra HD (i.e., 3840 x 2160 pixels with 30/60 frame per second).

Mobile Apps Threats

Donovan Peter Chan Wai Loon
University of Malaya, Malaysia

Sameer Kumar
University of Malaya, Malaysia

INTRODUCTION

In recent times smart mobile devices have become ubiquitous. More than half of all the mobile phones are now smartphones, and this statistic does not take into account the other devices such as tablets that are operating on similar systems (Gates, Chen, Li, & Proctor, 2014). With the abundant usage of smartphones, the way we go around our daily lives has certainly been transformed. The smartphones of today are more like mini computers than mobile phones of a few years back. Essentially, smart phones are computers with additional hardware—namely, a Global System for Mobile Communications or GSM radio and a baseband processor to control it (Miller, 2011).

Although this is great, there is also a threat emerging. In 2012 alone, Google estimated that more than 400 million Android devices had commenced operations. Android devices have been adopted widely for both personal and business use (Wang, Sun, Wang, & Jing, 2015). From adults to children, beginners to experts, and in numerous different countries around the world, there is a diverse user base for mobile devices (Gates et al., 2014). Attackers are now targeting these devices in the same way computers have been targeted for a long time. The extensive usage of mobile devices poses new threats to privacy and security of our digital lives (Zhou & Jiang, 2012; Zhou, Zhang, Jiang, & Freeh, 2011). Email messages, contact lists, passwords and files are often stored

both locally and in the cloud. Illegal access to this private information by any unknown parties puts users at risk. Threats become even more dangerous as these devices may provide deep insights by integrating our digital to our daily lives. The GPS unit can pinpoint exact information of our whereabouts, while the microphone can record audio and the camera documents images (Khan, Xiang, Aalsalem, & Arshad, 2013). Moreover, mobile devices are frequently connected directly to monetary risks, via SMS authentication messages, as a means to validate financial transactions, or directly linked to bank account through a ‘digital wallet’ (Gates et al., 2014). Getting access would mean that any application (app) that operates on the devices has the potential to tap into and to provide certain details of information of the users.

The purpose of this article is to gauge the trends and challenges posed by malicious mobile applications. Specifically the authors look at the some of the current research to detect malicious applications and remedy for poor risk communications on Android-based devices.

The rest of the paper is organized as follows: In Section 2 we provide a background on mobile threats from an adapted threat model. Emerging mobile threats and an overview of mobile malware for Android and iOS is presented in Section 3 followed by an example of detecting malicious apps presented in Section 4. Future research directions are discussed in Section 5. Section 6 concludes the paper.

BACKGROUND

Understanding Mobile Threats

In order to offer a wide indication of threats facing mobile devices, it is first important to understand the objectives, reasons and distribution techniques of potential attacks. In this paper, we adapted a threat model from prior research by Delac, Silic, & Krolo (2011 p. 2-3) and divided into two main components: attack goals and attack paths. This model is further supported by a similar study in the same year by Leavit (2011 p. 11-13) and has similar descriptions of the main components.

Attack Goals

Attack goals are motives for penetrating mobile devices. The objectives may be hidden or destructive intents. Hidden attacks are executed while eluding a user's detection. Destructive attacks on the other hand, are meant to interfere with the usual function of the mobile device.

- **Collect Private or Personal Data:** Attackers usually target confidential information stored on the device. An effective attack may permit the attacker with capability to read SMS messages, emails to contact details and call history. Additionally, attackers may retrieve classified information by accessing applications stored on the device. Furthermore, once the mobile device has been compromised, attackers may use the hardware features to gather extra data from an individual's environments. For example, the attacker may use the microphone to record audio, the camera to take photos and pinpoint a user's exact location information through the GPS component.
- **Exploiting Processing Properties:** Attackers target mobile devices for the raw processing capabilities. Most modern mobile devices come with high-powered CPU and multi core processors. Coupled with high

speed Internet connectivity, mobile devices are appealing for malicious activities, such as distribution of botnets.

- **Destructive Activities:** These actions are meant to cause distress to the mobile users compared to benefiting the attackers. While easy to detect, attacks of this nature are designed at causing as much harm as possible. The attacks may vary from data corruption, draining the battery from the device, and generating huge network traffic (Delac et al., 2011). Eventually, by acquiring controls to key systems, attacks could even deactivate the device rendering it useless.

Attack Paths

Attack paths are routes provided by mobile platforms for the distribution of malevolent packages. Mobile malware is malicious software developed particularly to attack mobile devices. Most attacks done are often a combination of several variants of mobile malware.

- **Mobile Network Services:** Initially, attackers used cellular services such as SMS, MMS and voice calls. False URL links are sent via SMS to unsuspecting users. When a user clicks the link, it automatically opens a browser allowing the device to be prone to an attack. MMS messages facilitated the delivery of malicious content through hidden codes embedded within the message as users downloaded the content. Voice calls on the other hand allowed attackers to maintain contact with the users by portraying to be a legal entity such as a bank asking for sensitive information such as credit card details. This act is also known as "phishing".
- **Internet Access:** Most modern mobile devices have Internet access through the use of mobile networks such as 3G/4G or Wi-Fi networks. The chance for an attack rises

if the mobile device is connected to public Wi-Fi network. The major weakness is hotspot architecture with no encryption to protect transmitted data (Leavit, 2011).

- **Social Networking:** New Internet services such as social media platforms are also prime areas for the spreading of malicious contents. For example, an attacker may spread harmful links on social media by masking it with topics of interest. Users may be misled to download harmful content or diverted to unauthorized sites.
- **Bluetooth and USB:** Bluetooth is used to spread malware from one device to another. For attacks to occur, the intended mobile devices must first be within range to enable the attacker to connect and send the malicious content. Attacks using this method are limited because of the by default most devices are not discoverable and requires authentication from the users to transfer and physical download the file. Another widespread attack is done using USB. Generally, a USB connection is used to pair mobile devices with computers for the transfer of files. Malicious content embedded in certain software applications is then transferred from the computer into the mobile devices.

Emerging Threats to Mobile Platforms

According to a report by Kaspersky Network Security Data, Kaspersky Lab products had detected 2,961,727 infections in 2015. There were a total of 884,774 new modifications of malicious programs targeting mobile devices; three times higher than the previous year. This indicates that the mobile malware segment has advanced swiftly in the past few years. Cybercrimes may have evolved from being acts of solo hackers to becoming an underground commercial organization. There are numerous kinds of players involved in the mobile malware industry: virus writers, testers, interface

designers the malicious applications and the web pages they are circulated from, and mobile botnet owners (Chebyshev & Unuchek, 2014).

Among the top trends for mobile malware in 2015 as highlighted by (“Mobile malware evolution 2015 - Securelist”, 2016) are: -

- **Evolution of Malware Towards Monetization:** Mobile Trojans targeting user bank accounts continue to grow with 7,030 new mobile banking Trojans detected in 2015.
- **Cybercriminals Actively Using Phishing Windows to Conceal Legitimate Applications:** One of the most notable examples is the Trojan-SMS.AndroidOS.OpFake.cc variation that is able to imitate the interface of 100 legitimate banking and finance applications.
- **Growth in the Volume of Ransomware:** Trojan-Ransom applications doubled in 2015 from the previous year, while new the amount of new modifications had increased 3.5 times. Another key indicator is the amount of people attacked in 2015, which increase five times compared to the year before.
- **Malware in Official Stores:** In October 2015, Kaspersky detected several Trojans in the official Google Playstore that stole passwords from the Russian social network VKontakte. Attackers had published these Trojans 10 times in the official app store using different names. The number of estimated downloads of these Trojans was between 100, 000 and 500, 000.
- **Malware for iOS:** 2015 saw the number of malicious programs for iOS increase 2.1 times compared to 2014. Contrary to popular belief, this demonstrated that iOS is indeed vulnerable to malware. Attackers did not hack the App Store but posted a malicious version of Apple’s Xcode. This had been spread in China affecting one of the most popular applications; a free mes-

senger “WeChat” installed on more than 700 million users devices. A Trojan was also detected in Japan using phishing techniques to steal money from users.

Among the nations in the world, China and Nigeria topped the ranking of countries facing malware with 37% in both countries (Chebyshev & Unuchek, 2016). Most of the attacks were from Trojan families and could lead to financial loss through withdrawals from mobile accounts of unsuspecting users. In addition to that, percentages of recorded attacks recorded also depended with the number of users in the country.

Mobile Malware: Android and iOS

Both iOS and Android offer a public marketplace for consumer applications. Apple has the App Store and Android uses the Google Play Store respectively. The two however adopt considerably different methods to minimize malware on their devices.

iOS

In standard Apple manner, the App Store is securely controlled from top to bottom. Apple must first endorse an application before it can be included in the App Store. Apple does this on the device by implementing code signing. iPhones will not be able to load an application or library if it's without Apple's private encryption key signature. Therefore only Apple knows how closely it reviews iOS apps. According to Miller (2011), Apple cannot be assessing the applications all that cautiously considering the number of applications, but any sort of review will remove the most apparent malware. Should a piece of malware manage to go through the review and enter the App Store, and users detect it, Apple could delete it from the App Store and the devices it was installed in. Although some may argue that the App Store is bad for developers, it has an efficient block to malware. Once installed on the device, applications operate

within a sandbox that limits their actions (Miller, 2011). For instance no application can read the saved SMS (short message service) messages, or one application cannot access another's data. All applications share common sandbox rules, so any action any application needs is approved. One example is that all applications can easily access the Internet.

Android

In the Android Market, developers are able to load their applications directly without any prior review done. Although Android phones need applications to be signed, they only require a partial signature. Google primarily uses the signatures for recording purposes and not to control the codes. Due to the open nature of Android, users may download apps from any source, not just the Android Market. For malware prevention, Android employs crowd sourcing instead of using the top-down approach. Applications are rated and commented by users. Users can see how many other people have used an application and can report any malicious applications to Google. If sufficient users give negative feedback regarding an application, Google will delete it from the market and from the devices. Android users are recommended not to ever download an application that does not have thousand of downloads and have mostly good comments. There have been several malicious Android apps, but most of them mainly existed in other markets than the Android Market. The openness of Android permits developers' ease of use but also but also allows easy entrance by malware developers (Zhou, Wang, Zhou, & Jiang, 2012).

When the application is on the device, Android too employs the sandbox model, however the sandbox is specific for applications. Before installation, applications will prompt users about which permissions are needed. These permissions can then be approved or declined by users. Applications that are declined will not be installed. One advantage is that these sandboxes can be personalized for each application instead of Apple's

method of one-size-fits-all (Miller, 2011). For example, a Calculator application does not require Internet access and so it will not be granted that access. The drawback, however, is that, in this model, users will have to make their own security decisions. These choices made are bad than good. Moreover, the reasons users are trying to install those applications are because they want them in the first place. This creates the tendency to click through the screens without doing much check on the requirements.

SOLUTIONS AND RECOMMENDATIONS

Detecting Malicious Applications (Android Market)

There are several researches done in detecting malicious applications in both official and alternative Android Markets. For the purpose of this paper, we selected the model design of “Droid Ranger” as proposed by (Zhou et al., 2012). The study aimed at presenting a logical way to understand and detect malicious applications of the overall Android Markets. It was conducted in June 2011 over a period of two months and covered a total

of 204,040 applications. The researchers used the following approaches in detecting malware:

- Permission-Based Behavioral Footprinting:** The scheme filters applications based on inherent Android permissions of malware and matching those with malware specific behavior.
- Heuristics-Based Filtering Scheme:** Defines suspicious activity of applications such as suspicious attempts to retrieve and perform codes from untrusted websites. Determines whether the application is benign or malicious based on monitoring runtime execution.

Design

To thoroughly identify malicious applications in the existing Android Markets, the researchers used three definitive design goals. The goals were accuracy, efficiency and scalability. Accuracy is a normal requirement of detecting negative malicious applications in the current market places. Efficiency and scalability were more complex. As described by Zhou et al. (2012) there were 200, 000 applications that needed to be scanned. It took two weeks to scan the entire collection.

Figure 1. Overall architecture of DroidRanger
Zhou et al., 2012.

Figure 1 illustrates a summary of the approach. DroidRanger collects applications from current Android Markets and stores them into a local repository. DroidRanger then extracts the fundamental properties of each application and analyses them according to the two approaches mentioned earlier. For known malicious malware, the DroidRanger categorized indexed them with the applications itself. Unknown malwares on the other hand were classified under “Zero-day Malware. A central database was used for effective indexing and lookup.

The research yielded good results and made a number of contributions. The first contribution was the DroidRanger pioneered a systematic study dedicated to detecting malicious applications on Android markets. Secondly was the extensive study of 200,040 Android applications. The researchers proposed two different schemes that allowed for efficient scalable detection of both known and unknown malicious applications. Finally, when applied, the DroidRanger had managed to successfully detect 211 malicious applications. Reporting from the researchers resulted in all those applications being removed from the Android marketplace and perhaps saving thousands of users from being affected by malicious malware

Effective Risk Communication for Android Applications

Recent efforts have tried to remedy some of the issues in poor risk communication towards android applications. Among the enhancements proposed by Felt et al. (2012) were to modify permission category headers, emphasize on risk, enable customized permission lists, incorporate user reviews, reduce the number of permissions and rethink the timing of how and when permissions permitted. Lin et al. (2012) suggested a method using crowd-sourced expectations of which authorizations are considered sensible and display it at the applications main description page. Kelley, Cranor, and Sadeh (2013) presented an idea of “privacy facts” which carries out at high-level types of information

an application has to access and display it on the applications main description page. However the present risk communication tools of Android are insufficient and lacking in terms of effectiveness. Users are still inclined to disregard the permissions that an application accesses.

In this section, the authors look into the alternative approach to the problem as recommended by Gates et al. (2014). The aim of the approach is to assist users to understand security and privacy consequences, aiding them to make installation decisions and reduce the amount of area used to show the risk information. Adding a short risk rating for the applications would enable users to compare risk among applications that have related functions. Gates et al. (2014) deduced that the main reason why users often ignored current permission information was due to way in which the information was presented. Information was in a separate section and required users to have a substantial amount of technical understanding. Users would also need much more time interpreting the information, thus creating problems in comparing applications. One significant feature in the Android ecosystem is that users have a wide selection and options when choosing a mobile application. Given the knowledge that a certain application may be riskier than another, which has the same functionality, the user may tend to choose the less risky application. Application designers will then conform and follow the fundamental standards by only requesting basic permissions.

Peng et al. (2012) offered a probable way for producing a principled metric to rank an application risk centered on the set of permissions it requests. The way it is done is that any Android application available Google’s online market (Google Play Store) is ranked in a summary risk rating. The risks are categorized into different values ranging from very low, low, medium and high risk. When a user looks for an application, the summary risk rating will provide brief information helping the user make an evaluation before proceeding to download the application. This is different from the current approach, where

Table 1. Risk rating experiments

Experiment	Testing	Results
1. Adding a risk metric	- Tested the amount to which having a risk category affects users' choices. - The behavior of users when were provided with the summary risk was compared to when there was no summary risk information.	Tests confirmed that specifying risk summary triggers users preference towards applications with lower risk
2. Safety versus risk	- Compared ease of processing the rankings in terms of risk or safety - Used an in-lab choice-	Results showed that responses were faster in the safety condition than the risk condition
	Reaction task for which response time and accuracy were measured.	
3. Safety versus risk with user ratings	- Similar to Experiment 2. - Displayed risk information and user ratings together in application context.	Mixed results showing responses were faster in the safety condition than in the risk condition. The interaction was not significant.
4. Safety versus risk in context	Determine whether symbolic presentation of risk influenced choices in a normal environment	Test confirmed overall participants chose the safer/less-risky apps more often

Conducted by Gates et al. (2014).

risk information of an application often appears to the user in the final stage when the user has already chosen the application. Gates et al. (2014) conducted four different experiments in testing their approach.

Table 1 summarizes the tests conducted.

In Experiment 2 and 3, the researchers had to decide beforehand which structure to frame the categories; either more symbols signify greater risk or more symbols signify better safety (safety dimension). Since users generally associate “more stars with being better”, the framing dimension used was that of the safety dimension. After conducting all four experiments, the hypothesis that when a summary risk rating is presented in a user-friendly fashion, it will encourage users to choose applications with lower risk had proved to be true.

FUTURE RESEARCH DIRECTIONS

The increasing usage of mobile devices today for numerous tasks such as online banking makes malicious malware very attractive for attackers. Hackers can now use various methods to launch attacks and steal financial data or cause financial loss. Mobile Malware has now evolved into a

moneymaking industry for hackers at the expense of unsuspecting users. In many cases, new modifications of mobile threats are constantly being developed and combined with ultimate goal of reaping profits from illegal sources.

The research has significance in that explains the main objectives, methods, and types of mobile threats faced by users today. Although research on mobile threats is rising, there are currently limited studies on how to overcome it. Available literature on the matter is focused on within the technology savvy community rather than the general public. This study is an attempt to highlight the mobile threats as well as create awareness amongst users on its detrimental effects.

There are several limitations with this study. In this research, only a model of detecting malicious applications via risk communication had been discussed. This could be enhanced through other studies such as biometrical security for users, which would more secure when downloading application. This research also only highlighted preventions on one mobile platform that was Android due to its popularity for mobile devices. For future research direction, an analysis including alternate platforms such as iOS may provide a better insight and understanding towards this study.

CONCLUSION

Smartphones are gradually becoming more and more valuable in our everyday life. They keep people connected and no one is ever lost or unreachable. The cutting-edge technology and functionality of this gadget has made it an appealing target for malicious and invasive applications. Even though solid security measures are there for most mobile infrastructure, the part where these systems often fail is the dependence on the user to make decisions that affect the security of a device. There is also a need for tighter policy procedures, especially for non-regulated alternative marketplaces.

KEY TERMS AND DEFINITIONS

Botnets: A Botnet is a set of infected devices, which can be ordered and managed remotely by an attacker. Attacks may range from sending spam mail to committing DOS attacks (Leavitt 2011).

Mobile Malware: (McAfee 2016) describes Mobile Malware as malicious software specifically aimed at attacking mobile devices.

Phishing: Phishing as “a type of attack that communicates socially engineered messages to humans via electronic communication channels in order to persuade them to perform certain actions for the attacker’s benefit” (Bottazzi et al., 2015).

Ransomware: Ransomware is a type of malware that severely restricts access to a computer, device or file until the user pays a ransom (Kaspersky Securelist, 2015).

Trojan: Trojans can be used to collect confidential information or to install other malicious applications like worms or botnets. Trojans can be also used to commit phishing activities. (Sujithra & Padmavathi, 2012).

Worms: Worms are self-replicating malicious applications designed to spread autonomously to uninfected systems. (Delac, Silic, & Krolo 2011).

Mobile Technologies Impact on Economic Development in Sub-Saharan Africa

Adam Crossan

Letterkenny Institute of Technology, Ireland

Kevin Curran

Ulster University, UK

INTRODUCTION

In today's world mobile technology has been used to help improve and enhance almost every sector, in this paper the author researches and discusses how it has helped benefit developing areas such as sub-Saharan Africa, the paper outlines the constraints of mobile technology in sub-Saharan Africa. This paper focuses mainly on how the use of mobile technology has improved the health and education standards in different areas. It outlines how mobile devices are being used to educate those all over sub-Saharan Africa on how to protect against diseases such as polio. This paper also details how mobile devices are being utilized to help provide better healthcare to those in African cities, through topping up smart cards with mobile devices for the distribution of clean water as well as the delivery of vouchers which can be exchanged for healthcare equipment. This report also discussed how mobile devices are being used to track and monitor the outbreak of malaria in sub-Saharan Africa and is applied to a system to help ensure health care facilities in areas with affected residents have the capacity to deal with those who have contracted the disease. Finally, this paper discusses the ethical effects of using the mobile devices and how they are affecting the residents of sub-Saharan Africa.

BACKGROUND

Mobile Technology is a sweeping term covering many different areas of technology. Many of the uses for this technology in developed countries include helping with general day to day operations for the user such as online banking, shopping, or social media applications. Mobile technology is a sector which is growing rapidly, and also merging with other sectors to help make use of the technologies full potential. One of the areas where mobile technology has been proven to be successful, is when using simple technology and mobile devices to help developing countries such as Africa (Aker & Mbiti, 2010). Many different organizations and companies are using mobile technology to accomplish huge feats for rural African villages. A leading success story has been the M-Pesa service launched in 2007 by Vodafone for Safaricom and Vodacom. This has generated mobile money revenues of more than \$300 million in 2004. This makes it the most successful mobile transfer service at this time. It has now expanded to Afghanistan, South Africa, India and Eastern Europe. It seems to have found its niche market. In Kenya alone, mobile money transactions totalled \$22+ billion in 2013. Other African countries such as Sudan, Somalia, Tanzania, and South Africa are also huge revenue generators for operators as well (BBC Africa, 2015).

Mobile Tech in Africa

In today's world when discussing developing countries, the most commonly mentioned country is Africa. Africa is known worldwide for its widespread poverty, levels of education, unsanitary living conditions, gang violence and high mortality, and birth rates. Many companies and organizations are now turning to mobile technology to help combat these issues facing those living in Africa. With the increase in advancements in technology, many organizations and companies are researching and looking into how some technologies could be adapted to help reach areas which are usually not easily accessible. A simple yet effective method at developing communication with these areas is through mobile devices. In recent years the ownership of mobile phones in Africa have increased rapidly, with the percentage of adults who own a phone rising from 64% in 2002 to now match the US with 89% in 2014 (Global, 2015). An infographic depicting this information can be seen in Figure 1. As shown in reports conducted by Pew Global (2015), the most popular activity for mobile phone users in Africa is sending text messages. The report shows that 80% adult cell phone owners use their phone mostly to send text messages as seen in Figure 2. SMS is arguably the most popular activity in this area due to the fact that many in this area only have ownership of a cell phone rather than smartphone, with a study conducted on Nigerian residents showing that although 89% of the population there owned a mobile phone only 27% owned a smartphone (Pew Global, 2015).

Constraints Affecting Mobile Devices in Africa

Africa is known for its lack of proper infrastructure, and industrialization. Technology isn't something that is commonly associated with Africa. The main contributing factor for this being that mostly all technology needs to be powered in some way. A study by The World Bank (2013), showing that

Figure 1. Percentage of what adults use their mobile devices for in sub-Saharan Africa
As stated by Pew Global (2015).

PEW RESEARCH CENTER

76% of sub-Saharan Africa is without access to electricity, the possibility of being able to use technology within these areas decreases drastically. Another area of technology which is obstructing the growth of use of technology in Africa is connectivity. A study by iPass, (2014) shows that if growth in connectivity hotspot numbers continue to grow at the same rate as previous years then by 2018 there will be a WiFi beacon for every 20 people on earth, however only one beacon for every 400 Africans.

Education

The use of mobile technology has been hugely influential in the improvement of education throughout Africa. The need for helping improve education throughout sub-Saharan Africa has been a main priority for many organizations, one of which was Oxfam. Oxfam are a charity organization which help in delivering medical aid, supplies and help to a number of different countries including Africa (Oxfam, 2016). One particular project which Oxfam began was to help improve sub-Saharan resident's knowledge on different diseases which were quite common in the areas however easily preventable. Oxfam developed an SMS delivery system, which would send out four texts daily with educational information on the different diseases and how to prevent against them. This was incredibly simple as the only technology needed for the residents was a simple mobile phone which could send and receive SMS.

Health

Mobile technology is also being used to help better the health services in areas of sub-Saharan Africa. Organizations and companies such as UNICEF are using simple mobile technology to help teach about how to prevent from contracting diseases, help improve distribution of medical supplies and equipment to people who would otherwise not have access to the materials. They are also helping to monitor and ensure medical facilities contain the

stock levels needed to combat against diseases. Two of the main diseases technology had been used to battle the spread of was polio and malaria.

Polio

Alongside the project discussed earlier to help better educate areas of Africa about the polio and how it can be contracted, a project was also launched that would help provide the equipment and sanitary supplies needed to help prevent the spread of the disease to rural and hard to reach areas. The project would also work through SMS where the users would receive a SMS with a mVoucher. As stated by Textello (2016), the mVoucher or mobile voucher is a unique code, each code is created using the customers contact number, resulting in each customer and code being linked, this then reduces the problem of multiple claims, and users mVouchers being stolen. The user would then present their code to a registered trader, where they would then in return receive the specified package containing the items and supplies needed (Oxfam, 2015).

Malaria

To help combat against the threat of malaria in different areas of Africa another project also using SMS was created. This project was however to help survey the outbreak of the disease, and help get real time accurate updates on the impact of the disease. A system to combat malaria such as this was needed as malaria is still a large threat, particularly to children as indicated by the World Health Organization (2015), detailing that a child dies every two minutes in sub-Saharan due to malaria. Rather than simply just supplying information on the disease and vouchers for equipment to prevent from contracting the disease like done with the polio SMS system, the new system would "improve access to essential malaria medicine in areas of developing countries" (Novartis, 2014). The new SMS system created was called "SMS for life". SMS for life uses common technology

to help achieve its goals of eliminating medical facilities from depleting stock levels completely, increase access to essential medicines needed for those infected with the disease and to help reduce the amount of deaths caused by malaria.

SMS for life is a web based system which makes use of a SMS management tool, this then links with a web based application created for reporting. The system uses the SMS management tool to store the number of a health worker from each of the medical facilities registered in the area, SMS for life then uses a short code number that allows the health facility employee to receive an SMS with a data request, and send an additional SMS with the requested data counts completely free. The data sent from the health worker is then manipulated by the online reporting system, which makes it available for viewing online by a higher body, usually the District Health Management Team. The higher body view this information on the SMS for life website by password, this allows a secure method of monitoring the malaria surveillance in each medical facility in the area (Githinji, et al., 2014).

Water ATM's

In some areas in Africa, local governments have teamed with Grundfos, a Danish water engineering company to install “water ATM’s”. The water ATM’s work by have having a water dispenser installed with users having an account with the dispenser. Each user then receives a smart card, these smart cards and accounts are topped up through mobile phones. The water dispensers can then be activated by the smart card. The user simply scans or swipes the smart card to be dispensed clean, safe water (Wesangula, 2016).

This project has brought water to many different areas of rural Africa and has now began to be installed in more urban areas such as Nairobi (BBCAfrica, 2015). As stated by Mourdoukoutas (2015), there are still some issues with the systems however Rasoul Mikkelsen, Grundfos director for global partnerships believes that “he project

will have a huge positive impact on health. It is an affordable system with sustainable, good quality water,”.

As well as the projects discussed above there have also been systems developed using SMS to help monitor Zambia for measles outbreaks, allow HIV sufferers health workers to send information on patient status as well as inform their patients details of their anti-retroviral therapy (Aker & Mbiti, 2010).

Ethical Effects

It is clear to see that the results of the Polio projects mentioned above have been extremely successful. An evaluation report by Oxfam (2015) stated that the project had a reach of 104,358 residents receiving the text which in turn was estimated with a reach of 1 million people, this was a completion rate of 86%. These people are now much more educated on how to better protect themselves against Polio, giving not just those who received the informative SMS messages but also those who were in communication with them, a better standard of living and a greater opportunity at life. Also with the pairing of the mVouchers for sanitary supplies and equipment to prevent contraction, with the educational messages it gives an incentive, as it gave the participants of the scheme something physical alongside the messages, something that they can then use the information received to put into practice (Oxfam, 2015).

However, there were some issues surrounding the project. The mVoucher system feedback report shows that the amount of participants that received the voucher compared to the amount of vouchers collected varies greatly with 71.4% of those who received a voucher declining to redeem it (Oxfam, 2015). Oxfam distributed a household survey to each of those who participated in the project, the survey asked the participants if they had collected their supplies with the voucher and if not then why? The main reason given for not claiming the supplies was “Distance to distribution Centre”, this highlights how these projects

seem to be specifically targeted at more urban areas rather than the outer lying rural areas of sub-Saharan Africa which is usually in greater need of the aid. This can also be seen in the number of distributors in each district, when the project began it was outlined that each district was to have 3 traders and 15 distributors, however this did not happen in every district, because of the lack in distributors the resulting distribution was below expected capacity, with fewer distribution points (Oxfam, 2015).

Issues can also be seen with the water ATM's which have been implemented in certain cities throughout Africa. Although the ATM's have achieved their goal of delivering safe clean water to different parts of the city, they too can be seen to be focused on the urban areas. As discussed in an article by Mourdoukoutas (2015), it states that Mr. Gichuki, the managing director of the Nairobi Water and Sewerage Company, said that "the Nairobi Water and Sewerage Company has so far identified 611 more points to install the dispensers and aims to eventually install one every 100 meters throughout the city". Meaning the residents from more rural secluded areas are left having to travel further for clean water when those who live in the cities have multiple choices for where to receive their water from, as well as having to wait longer before the installation of a water ATM in a nearer location. This again shows the imbalance between the urban and rural parts of sub-Saharan Africa.

FUTURE RESEARCH DIRECTIONS

The effects of the increased use of mobile technology can be seen in many areas, and with numbers showing that Africa has had the fastest growing region in the years 2009 to 2014, and as stated in a report by GSMA intelligence (2014), is predicted to continue to grow at a rate of 7% annually until 2020. These figures show the level of growth expected for Africa however when looking at figures relating to each individual country a drastic imbalance can be seen. As shown in the report by

GSMA intelligence (2014), the breakdown of the number of subscribers to mobile phone providers show the harsh difference between the more urban countries and the more rural countries. For example, the percentage of subscribers in Mali is 70%, compared to the considerably smaller percentage of 22% in Ethiopia. This large margin shows the growing issue of the difference between these two areas, an issue which needs to be examined. As stated in a report by Aker & Mbiti (2010), more examination of the possible impacts that could occur is needed, the report suggested that "careful evaluations of mobile phone development projects are required for better understanding of the economic and social outcomes".

CONCLUSION

From researching and examining how mobile technology has helped improve sub-Saharan Africa, in the different areas of health and education, it is clear that the technology and the projects it was used in has greatly benefited the African residents. The educational system created to aid those at risk of polio helped residents learn cleaning procedures and how to use the sanitary items provided with the mVouchers also distributed through mobile devices also. The use of mobile devices has also helped service those suffering from malaria, as it ensures that those needing treatment's local health facility will always be within capacity, thanks to the "SMS for Life" system. Finally, the statistics outlining the difference from the rural and urban areas of sub-Sahara, show how the effect differs from region to region. To conclude the paper, it is evident from the information presented that mobile technology has greatly helped improve different areas of life such as education and health. However conversely the effects of the increased use of mobile devices in Africa has contributed to a poverty imbalance and perpetuating health inequalities between the urban and rural areas of sub-Saharan Africa, and its possible impacts is an area that needs to be greatly researched before any implementation of larger projects can begin.

KEY TERMS AND DEFINITIONS

Advance Fee Scam (Nigeria 419): An advance fee fraud which involves a payment in advance with the promise of wealth, wills, gifts, employment or prizes. The scammer contacts their intended target via mail, phone, fax or email. Originally known as the Spanish Prisoner Letter it has been carried out since at least the 16th century via ordinary postal mail. Section 419 of the Nigerian Penal Code prohibits this type of activity and it has often referred to as ‘419 frauds’ or ‘Nigeria 419’.

Developing Countries: Often referred to as underdeveloped countries and they refer to countries where there is a less developed industrial base and they have a low Human Development Index (HDI). Developing countries differentiate from developed countries in that the people have a lower life expectancy, lower standard of education and the people of developing countries have a lower income and thus less money.

Ethical Standards: Principles which when followed will promote values such as trust, good behaviour, fairness and/or kindness. One consistent set of standards that all companies follow does

not exist but rather each company has the right to develop a set of standards which are meaningful to that particular organization.

Information and Communication Technology (ICT): An umbrella term which includes any communication device or application, encompassing: radio, television, cellular phones, computer and network hardware and software, satellite systems and so on, as well as the various services and applications. The term ICT however has no set definition as the concepts methods and applications involved in ICT are constantly changing almost on a daily basis.

Mobile Point of Care (MPOC): Involves the use of multitasking devices which support clinician use cases, improve productivity, streamline communication and bridge the gap between in-patient and outpatient care. This fast growing area provides an abundance of apps for mobile devices and will change the way healthcare is delivered providing the opportunity for remote monitoring, measuring drug response, tools for drug development and diagnostic assistance for point-of-care and management of chronic or infectious disease.

Mobile Technology: A technology which is used for the purpose of cellular communication. The standard mobile device has moved from being

a simple two-way pager to being a mobile phone. Mobile technology as the name implies refers to a technology which is portable. Examples of mobile IT devices include: laptops, netbook computers, tablets, smart phones, global positioning system (GPS) devices

Personal Data: Data relating to a living individual who is or can be identified from the data or using the data in conjunction with other information which is in or likely to come into the possession of the data controller.

Short Message Service (SMS): A simple text messaging service component found in phones, the Web, or in mobile communication systems. It adopts a series of standardized communications protocols which enables either fixed line or mobile phone devices to exchange short text messages. More commonly referred to using the term “SMS” it is used for both user activity and all types of short text messaging in many parts of the world.

Sub-Saharan Africa: Geographically refers to all the areas of the continent of Africa which lie south of the Sahara Desert. Some of the countries which fall into this category include countries such as Kenya, Ethiopia, Ghana, Nigeria and South Africa.

Mobile Virtual Reality to Enhance Subjective Well-Being

INTRODUCTION

Focusing on health-care, in the last few decades advanced technologies have become crucial keys in supporting subjective well-being (Botella et al., 2012; Riva et al., 2012). Among them, Virtual Reality (VR) - defined as three-dimensional, stereoscopic, interactive computer graphics — has been proven effective in promoting mental health at different levels. In particular, several research studies showed the efficacy of VR in stress management (Gaggioli et al., 2014; Pallavicini et al., 2013; Rizzo et al., 2012; Serino et al., 2014) and in the treatment of different disorders; these include phobias (Parsons & Rizzo, 2008; Rothbaum et al., 1995), anxiety (Meyerbröcker & Emmelkamp, 2010, 2011; Pallavicini et al., 2009) and eating disorders (Ferrer-García et al., 2009; Riva, 2005). This technology is also adopted in neuropsychology, for both the assessment and training of cognitive processes (Cipresso et al., 2014; Fordell et al., 2011; Raspelli et al., 2012).

Although the dramatic development in the field of VR systems, there are still important problems related to the use of this technology (Pallavicini et al., 2015; Proffitt & Lange, 2015). First, from a technological point of view, VR are not so easy to be used, requiring a specific training for the clinician and the patient. Secondly, from a clinical perspective, these technologies are not easy to be moved at patients' home, where the delivery of interactive exercises may be useful, especially when patients are provided with a rehabilitative training (Pallavicini et al., 2015).

Within this perspective, the growing availability, low-cost and easy-to-use of Mobile Virtual Reality (MVR) (i.e., the integration of VR system on mobile devices such as smartphone and tablet) represents a meaningful opportunity to support mental health interventions (Gaggioli et al., 2014; Gorini et al., 2010; Pallavicini et al., 2009). MVR, in particular, can offer to the community an innovative tool for the management, monitoring and delivery of exercises, that can

also be used in individuals ‘favorite environment’, their home (Pallavicini et al., 2015; Tong et al., 2015; Schroeder et al., 2013).

The present chapter will first briefly describe MVR, highlighting the specific features that characterize it. Then, a MVR design practice will be presented. In conclusion, the current application of MVR to enhance subjective well-being will be discussed, with the support of concrete examples and research studies-analysis.

BACKGROUND

VR is a high-end user-computer interface that involves real-time simulation and interactions through multiple sensorial channels (Burdea & Coiffet, 2003). Although many authors have defined VR essentially as a technology (Heim, 1998), more recent approaches (Riva et al., 2007) forward a more complex vision, considering VR as a human experience and underlining how “the essence of VR is the inclusive relationship between the participant and the virtual environment” (Fitzgerald & Riva, 2001).

VR can be presented in at least five ways:

- **Fully Immersive VR:** It consists of 3D simulation that allow participants to observe and interact with an environment through an available set of actions. With this type of solution, the user appears to be fully inserted in the computer-generated environment. This illusion is rendered by providing a Head Mounted Display (HMD) with 3D viewing and a system of head tracking, to guarantee the exact correspondence and coordination of user’s movements with the feedbacks of the environment;
- **Desktop VR:** It consists of computer-generated environments, which exist in 3D (even if they are shown on a 2D display). It uses a computer monitor as display to provide graphical interface for users. It is cost-effective when compared to the immersive

VR as it does not require any expensive hardware and software and is relatively easy to develop. Interaction with the interface can be made via mouse, joystick or typical VR peripherals such as Dataglove;

- **Augmented Reality:** The user’s view of the world is supplemented with virtual objects, usually to provide information about the real environment;
- **Mixed Reality:** Sometimes referred to as hybrid reality, refers to the merging of real and virtual worlds to produce new environments and visualizations where physical and digital objects co-exist and interact in real time;
- **CAVE:** The term stands for CAVE Automatic Virtual Environment and takes the form of a small room where a computer-generated world is projected on the walls. The projection is made on both front and sidewalls. This solution is particularly suitable for collective VR experience because it allows different people to share the same experience at the same time;
- **Telepresence:** Users can influence and operate in a world that is real but in a different location. The users can observe the current situation with remote cameras and achieve actions via robotic and electronic arms.

From about 2007, the year in which Apple presented the first model of iPhone and the mobile industry significantly changed - thanks to the new possibilities offered by smartphone and tablet to integrate VR, MVR has been risen.

MVR can be defined as “the integration of VR environments on mobile devices” (Pallavicini et al., 2015), and it can be divided into two sub-categories based on its technical features:

- **Screen MVR:** It uses the mobile screen as display to provide 3D virtual environments, even if they are shown on a 2D display;
- **Immersive MVR:** The user is completely immersed in the computer-generated en-

vironment by providing a Head Mounted Display (HMD) designed for mobile phones, like Samsung Gear and Google's Cardboard VR.

HUMAN COMPUTER INTERACTION AND DESIGN PRINCIPLES FOR MOBILE VIRTUAL REALITY

A central task in the design of MVR is to create scenarios and tasks that could be effective, engaging (and usable) within and across different contexts (e.g., clinic and home). Thus, an interdisciplinary approach including users, trainers, designers, psychologists and technology experts can define concrete guidelines, may support strategic choices and training design activities evaluation.

To this end, much can be learnt from Interaction Design Research (e.g., Stolterman, 2008), which offer general principles for Human Computer Interaction (HCI) or “the region of intersection between psychology and the social sciences, on the one hand, and computer science and technology, on the other” (Carroll, 1997). In other words, HCI is a science of design, aimed to understand and support human beings interacting with and through technology. Within HCI, a specific area is focused on VR systems, defined as “Human Virtual Environment Interaction” (HVEI) (Bainbridge, 2007; Stanney, Mourant, & Kennedy, 1998).

During the design of MVR scenarios, technology and users-related variables are equally important to be considered (Harrison et al., 2013). In fact, due to the close bond between the user and the system, is impossible to segregate human factors from design issues when striving to achieve the potential of MVR technology. It is the capabilities and limitations of the user that often will determine the effectiveness of virtual worlds.

- **Technology-Related Variables:**

- **Fidelity:** This term refers to the extent to which the virtual environments emulate the real world (Alexander,

Brunyé, Sidman, & Weil, 2005). In other words, it can be defined as the objective level of sensory realism a VR system provides. Physical fidelity can be achieved and developed on different levels: visual, auditory and haptic. MVR systems vary in their degree of physical and functional fidelity based on technical feasibility, cost, and needs. Obviously, it is not possible to simulate the physical world in all its details and complexity.

- **Users-Related Variables:**

- **Usability:** Is defined as the extent to which a product can be used, by specified users, to achieve specified goals with effectiveness, efficiency and satisfaction, in a specified context of use. Usability is often defined as a quality attribute, which determines how the interface is easy to use by users. Following the definition, it is possible to assume that a good usability can be crucial to provide a good user experience. However, depending on the context, the system may have a good user experience without good usability, since several other areas such as aesthetics, fidelity, interactivity and presence are related (Garrett, 2010; Shneiderman, 2010; Sutcliffe & Kaur, 2000).
- **Sense of Presence:** Presence is widely accepted as the key concept to consider in any research involving human interaction with VR systems. Presence has been used as a global experiential quality metric to evaluate, develop, and optimize virtual environments and media systems (Riva, Waterworth, Waterworth, & Mantovani, 2011; Riva et al., 2007; Stanney et al., 1998). Factors connected with the possibility to develop the sense of presence experience by

Figure 1. Usability framework

users can be included in five main areas: (1) media characteristics; (2) perceptual features; (3) individual factors; (4) content characteristics; (5) interpersonal, social and cultural context.

- **Cybersickness:** In some cases, users develop symptoms that are similar to

the common symptoms found when people get motion sick. Users who exhibit these type of motion sickness-like symptoms suffer from a malady called cybersickness. A number of symptoms can occur due to cybersickness (LaViola, 2000; Vinson, 2012).

Figure 2. Developing presence

Regarding the process of the design of MVR scenarios and tasks is a complex and iterative process that should include different phases that could be summarized as following (see Table 2):

1. **Comprehension Phase:** During this first stage, ‘what the MVR system must do’ (i.e., what features should have and how it should adapt to other elements) and requirements are defined. To identify the requirements is necessary to collect information about the
- final users, the other stakeholders (i.e., all the people who will be affected by the system), and the contexts in which the MVR will be used (i.e. Immersive VR versus Screen VR). The requirements to be defined include those: (1) non-functional (i.e., what the system must be able to do), and (2) functional (i.e., the reality of what is technically feasible).
2. **Design Phase:** It includes two different types of design activities, and in particular: (1) conceptual design, that is the design of

Table 1. Designing MVR for subjective well-being: steps and guidelines

Step	Description	Main Questions You Have to Ask Yourself
1	Define the goals	• What do I want to achieve? • Is my goal SMART (specific, measurable, achievable, relevant, time-bound)? • What are the skills I want to assess/train? • How can I define each one of these skills? • What is my target? • What is the impact this goal is going to have on my target?
2	Select objectives that can use MVR for attainment	• Why should I use MVR to assess/train these skills? • How can I assess/train these skills with a MVR system? • What are the competitive advantages if a MVR system is used?
3	Refine selection, choosing those that can use MVR	• Among all the skills I want to assess/train, which are the most suitable MVR? • Why do I have to choose them?
4	Perform substeps for each objective	• How can I achieve my goal? • Are there any other subordinate goals? • What are the tasks users need to complete in order to achieve each subgoal? • What are the steps required to achieve the goal?
5	Choose MVR software/hardware and/or delivery system	• Is fidelity important for my goals? • What kind of fidelity (physical, functional, equipment, psychological) do I have to enhance? • How can I enhance it? • What type of immersion and presence is required? • What kind of interaction is required?
6	Design and build the MVR scenarios	• What knowledge and skills are required to produce the required behavior given the information provided? • Do the color and texture matter? What are the critical appearance attributes? • What aspects of behavior have to be produced to generate interactions? • What sounds have to be produced and to what degree of fidelity?
7	Evaluate the MVR scenarios with a pilot group	• Can a pilot group achieve the main goal? • Which tools and measure can I use to evaluate MVR efficacy?
8	Modify the MVR scenarios according to evaluation. Repeat 7 & 8 until satisfactory	• Is the system usable? • Do users experience cybersickness? • Do users experience a sense of presence in the environment?
9	Evaluate the MVR scenarios with a target population	• Is the system effective? • Which tools and measure can I use to evaluate MVR efficacy? • What are the main variables I have to consider?
10	Modify according to results. Repeat 9 & 10 as needed	• Is the system usable? • Do users experience cybersickness? • Do users experience a sense of presence in the environment?

a system from the abstract point of view; (2) physical design, the concretization of ideas and the definition of operating details and interface design, with particular attention to ways of interaction (interaction design) and layout (aesthetic).

3. **Envisionment Phase:** At this stage, it is necessary to represent the design ideas to demonstrate the feasibility of ideas. The MVR project can be represented in different display modes including the creation of storyboards, prototypes, sketches (Davies, 2004).
4. **Evaluation Phase:** Any design and envisionment activities is followed by the evaluation phase, which has the purpose to verify the effectiveness of the MVR scenarios. There are several techniques, including the creation of specific scenarios of use (Sutcliffe & Kaur, 2000).
5. **Implementation Phase:** Development and validation of the MVR system. Essential to check that the entire system complies with the requirements laid down and to be able to launch and complete.

SOLUTIONS AND RECOMMENDATIONS

As already pointed out in chapter, MVR is a young technology, in particular as regards the Immersive MVR. For this reason, still few studies have tested the effectiveness of this technology for enhancing subjective well-being (e.g. Pallavicini et al., 2009, Gorini et al., 2010, Tong 2015). Below the MVR app tested so far for mental health will be presented.

- **Anxiety Disorders:** The first clinical interventions for subjective well-being using MVR was developed for the treatment of General Anxiety Disorder (GAD) (Gorini et al., 2010; Pallavicini et al., 2011). Patients were given a smartphone (HTC

Touch Pro T7272) in which they can experience a relaxing scenario, achieved by presenting virtual environments (i.e., campfire, waterfall, beach and a gazebo) for relaxation homework. Results show the efficacy of this mobile technology in the treatment of GAD and the advantage for patients to set a guided relaxing experience using a mobile device (Gorini et al., 2010; Pallavicini et al., 2009; Repetto et al., 2011).

- **Stress:** Positive Technology is a mobile application developed for stress management (Gaggioli et al., 2014). It included three different components: (1) Guided Relaxation, that consisted of four 3D interactive environments and six relaxing music, designed to support relaxations; (2) Biofeedback, in which heart rate data detected in real-time modified the size of virtual objects (fire, waterfall) in the virtual scenario; (3) Stress self-reporting and tracking, where the user can report stress level or let the app heart his/her heart rate values.
- **Pain:** A technological solution, integrating MVR within the theoretical perspective of mindfulness (a form of meditation teaching present-moment awareness) has been developed by Schroeder and colleagues (Schroeder et al., 2013). Unity 3D for iOS system was used to develop the software for a solution consisting of separate virtual cameras, tied to each of the two rendering viewports displayed on the phone. The result is a set of three scenarios: (1) the Mindful-Movement Environment, that recreates a mindful walking, with the related body perceptions within a calm garden and ambient sounds scenario; (2) the Engaging-Multiple-Senses Environment, which integrate also auditory, visual and haptic stimuli, directing the attention to present perceptions offered by the five senses; (3) the Lying-down Guided-rest Environment, to facilitates visualization exercises while

Table 2. MVR current applications to enhance subjective well-being

Area	Study	MVR App	Operating System	MVR Scenarios
Anxiety	• Pallavicini, 2009 • Gorini, 2010	INTREPID system, virtual environments for relaxation and biofeedback training	Windows Mobile	Four virtual environments (campfire beach, waterfall and gazebo).
Stress	Gaggioli, 2014	Positive Technology -App for relaxation and biofeedback	iOS (iPad 2/New iPad and iPhone 4/5)	Five environments (island landscapes for relaxation, with fire and waterfall for biofeedback).
Pain	Schroeder, 2013	Virtual scenarios for pain management with tactile body sensors	iOs (iPhone 4)	Three environments (mindful-movement, engaging-multiple- senses, lying-down guided-rest).
Pain	Tong, 2016	Cryoblast - First-person shooter game for self-pain management	Android system, played via Google Cardboard (Do It Yourself VR)	Six environments (six different types of cave as game scenarios).
Neglect	Pallavicini, 2015	NeglectApp - App for the assessment of the disease	iOs (iPad 2)	Three environments (Neglect App cancellation tests, Neglect App card dealing task).

lying down, detecting psychophysiological parameters. Recently, Tong (Tong et al., 2015) developed a MVR solution for self-managing of pain, called Cryoblast. This pain distraction game has been developed for Google's Cardboard and works on mobile phone as a first person shooter. The players are virtually turned into the character of the game that has to go through six environments (virtual caves) and two kinds of games (fighting enemies and collect items). Enemies are the cells responsible for pain that the player has to defeat, using analgesic drugs as weapons, shooting through the Cardboard magnetic button.

- **Neglect:** Recently Pallavicini et al. (Pallavicini et al., 2015) developed a MVR app for iOS system, called NeglectApp, for the assessment of Neglect. This app contains a series of test for the evaluation of the USN using interactive virtual environments. Specifically, the app includes two different categories of tasks: (1) Neglect App cancellation tests, which are designed to recreate the traditional paper-and-pencil cancellation test, played within the application in a three-dimensional version; (2) Neglect App card dealing task that recre-

ates a virtual environment in which the patient has to give three cards for a game to himself/herself, to each one of the three individuals seated and four in the middle of a table. Neglect App test were carried out with the aid of a stylus for touchscreen, on an iPad2. A scientific evaluation reported that the tests made with the app are equally effective to the traditional ones (Pallavicini et al., 2015).

MVR can play a significant role to support subjective well-being and mental health care. Through the growing availability of cheap and safe devices, MVR is becoming a mass consumer product, and moving to the home. This implies that MVR can provide innovative opportunities to design and to shape the continuity from the real to the virtual (and vice versa), in both training and assessment, in a variety of application domains (from the clinical, or the neuropsychological, to the learning one). It is not a matter of generating a seamless continuity from the real to the virtual. The aim is to combine simulations in the real with simulation in the virtual, in a serial fashion and in a way that allows researchers to assess the integrative process carried out by perceivers over time.

FUTURE RESEARCH DIRECTIONS

In the future, it would be interesting to develop MVR scenarios and tasks that exploit the full potential of this technology, using its unique features of navigation, realism and interactivity. Secondly, it could be useful to study the possibility offered by MVR in training and rehabilitation program for mental health-care. Such technology, in fact, could make patients' homework and tasks more engaging, and consequently more effective, than traditional ones. Potentially, moreover, data collected about exercises made on tablet (scores at each task, frequency of use, etc.) could be tracked over time and integrated with other patient information, providing important information to the clinician.

To this end, it will be important that future studies will be aimed to: (1) scientifically test the effectiveness of this innovative technology for personal empowerment and well-being; (2) investigate aspects of User Experience related to MVR, in order to define which are the unique aspects of this technology, compared to other traditional tools, and to provide useful guidelines for the design of this type of application.

CONCLUSION

A recent Goldman Sachs research report predicts the VR industry may soon become an \$80 billion market (\$45 billion in hardware and \$35 billion in software) by only 2025. Since MVR is still a new and developing space, analysts say the forecasted \$80 billion is likely to waver according to actual adoption rates among enterprise and consumer users.

In light of such steep growth rates and innovation, VR and MVR will probably create new industries and change existing ones, including the mental health-care industry. Designing usable and effective interactive MVR system in supporting subjective well-being in a more engaging way

than usual care programs - and consequently potentially more effective - will be the challenge to overcome in the next years.

Furthermore, efforts will be needed before MVR can become part of clinical practice; however, the growing availability of this easy-to-use and low-cost technology can be a great challenge to support subjective well-being and mental health care programs.

KEY TERMS AND DEFINITIONS

Desktop VR: Computer-generated environments which exist in three dimensions (even if they are shown on a 2D display).

Fidelity: The extent to which the virtual environments emulate the real world.

Fully Immersive VR: Three-dimensional (3D) simulation that allow participants to observe and interact with an environment through a head mounted display with 3D viewing.

Immersive MVR: A MVR system in which the user is completely immersed in the computer generated environment by providing a Head Mounted Display (HMD) designed for mobile phones.

Mobile Virtual Reality (MVR): Integration of Virtual Reality system on mobile devices such as smartphone and tablet).

Screen MVR: A MVR system in which that uses the mobile screen as display to provide 3D virtual environments, even if they are shown on a 2D display.

Usability: The extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use.

Novel Methods to Design Low-Complexity Digital Finite Impulse Response (FIR) Filters

David Ernesto Troncoso Romero
CONACYT at ESCOM-IPN, Mexico

Gordana Jovanovic Dolecek
Institute INAOE, Mexico

INTRODUCTION

A discrete-time signal is a sequence of numbers, so-called samples. A sample lasts T_s seconds, then another sample appears during the next T_s seconds and so on, forming the sequence. The time T_s is called sampling period and the number produced in the n -th sampling period (i.e., after n times T_s seconds) is denoted as $x(nT_s)$. For analysis purposes it is usual to assume that $x(nT_s) = 0$ for negative values of n and, in general, the samples can be *complex numbers*. If so, the signal is a complex signal. In these analyses, the digital frequency f is a value that expresses how much of a cycle of a sinusoidal wave is represented by a sample. In general terms, discrete-time signals may contain information for different values of f .

A digital filter is a system that receives a discrete-time signal and returns another discrete-time signal with modified characteristics (Antoniu, 2006). Many digital filters exhibit the *Linear Time-Invariant* (LTI) property. When the input signal $x(nT_s)$ has the value 1 for $n = 0$ and 0 for other values of n , the output signal of a LTI digital filter is called impulse response. LTI digital filters are often classified by the duration of its impulse response as Infinite-duration Impulse Response (IIR) or Finite-duration Impulse Response (FIR) filters (Tan & Jiang, 2013). Additionally, a LTI digital filter is generally described by its frequency response, which is the response of the filter to a *complex exponential signal* with frequency $2\pi f$. The frequency response is a *complex function* of f

and is periodic over f , with a period of $1/T_s$. Because of this periodicity, the frequency response is just observed in the range of values from $f = -1/2T_s$ to $f = 1/2T_s$. As a complex function, the frequency response has two functions associated with it: its *magnitude response* and its *phase response*.

When the values of the impulse response are real, the magnitude response is symmetric and the phase response is anti-symmetric around $f = 0$ (Taylor, 2012). Thus, these responses are just observed in the range of values from $f = 0$ to $f = 1/2T_s$. Systems with real impulse response are used in a wide variety of applications, being one of the most common the traditional low-pass filter. This filter passes the frequency components of the input signal that range from 0 to f_p and rejects the frequency components of the signal that range from f_s to $1/2T_s$, with $0 < f_p < f_s < 1/2T_s$. The values f_p and f_s are the passband edge and the stopband edge frequencies, respectively, whereas the range from 0 to f_p is the passband, the range from f_s to $1/2T_s$ is the stopband and the difference $f_s - f_p$ is the transition band. The ideal values of the magnitude response in passband and stopband are, respectively, 1 and 0. For a realizable filter, an acceptable deviation from these ideal values must be specified. Usually, these deviations are represented as the numbers δ_p and δ_s , respectively. Figure 1 shows the specifications of the magnitude response of a low-pass filter, along with the ideal response and the actual magnitude response of the filter, denoted as $|H(f)|$. For analysis purposes it is usual to assume $T_s = 1$, i.e., $x(nT_s) = x(n)$.

Figure 1. Magnitude response specifications of a low-pass filter

Thus, in Figure 1 the range of interest of values f is from 0 to $1/2$.

Digital FIR filters play a central role in modern Digital Signal Processing (DSP) systems. These filters find extensive applications in communication systems, audio systems, instrumentation, image enhancement, processing of geophysical signals, processing of biological signals, among others (Antoniou, 2006). This is mainly due to the advantages of FIR filters, being the most important (Taylor, 2012):

- Absolute stability.
- The fact that FIR filters can be designed to have linear phase response.

The main disadvantage of conventional FIR filter designs is that they require, especially in applications demanding narrow transition bands, a high number of arithmetic operations and hardware components. This makes the implementation of FIR filters with narrow transition bands very costly (Taylor, 2012). However, several methods to design low-complexity FIR filters have been developed over the past three decades, approximately. One of the most popular approaches among them consists on designing an overall filter as an interconnection of simple subfilters, where some of these subfilters have a frequency response with one or more of its periodic shapes, so-called im-

ages, appearing into the range $0 < f < 1/2$ (in other words, the period of the frequency response of these subfilters is $1/2$ or smaller). These methods are classified as “frequency response masking methods”. This approach is adequate from a low power consumption perspective, since the subfilters are simple and the overall filter performs a lower number of computations in comparison to a direct design.

The design of low-complexity FIR filters is a challenging task since many aspects have to be taken into account. The efficient design of FIR digital filter needs a trade-off between very stringent design specifications, low power consumption, low area requirements, high speed of computations and low time and design effort. An acceptable design should balance the trade-off to a reasonable degree. Thus, in this chapter we introduce a review of methods employed to efficiently design low-complexity linear-phase FIR filters.

BACKGROUND

A FIR filter produces a signal $y(n)$ as follows,

$$y(n) = \sum_{k=0}^N h(k)x(n-k) \quad (1)$$

where the integer N is the filter order and the values $h(k)$, with $0 \leq k \leq N$, are the samples of the impulse response of the filter. A FIR filter has a linear phase if its impulse response satisfies either $h(k) = h(N-k)$, which is called condition of symmetry, or $h(k) = -h(N-k)$, which is called condition of anti-symmetry, for $0 \leq k \leq N$. Figure 2 illustrates the impulse response of a symmetric filter for N even.

The direct-form implementation of a symmetric filter for N even is presented in Figure 3. The filter consists of three types of digital circuits: *multipliers*, *adders* and *delays*. Among them, multipliers are the most critical blocks in terms of power consumption and speed of operation

Figure 2. Impulse response of an N -th order symmetric filter, with N even

(Aksoy, Flores & Monteiro, 2014). The values of the impulse response of the FIR filter are physically implemented in the structure, and they are usually referred as coefficients of the filter. The direct-form implementation of a symmetric (or an anti-symmetric) filter requires approximately N adders, N delays and $N/2$ multipliers. The number of arithmetic operations that a filter performs to obtain an output sample is the computational complexity of the filter. For the aforementioned filter, this complexity is N additions and $N/2$ multiplications. Clearly, the complexity increases proportional to N . The computational complexity is proportional to both, the power consumption of the filter and the speed of operation. Thus, this complexity must be decreased in practical applications.

The minimum order of an optimum linear-phase FIR filter meeting the low-pass filter specifications $(1-\delta_p) \leq |H(f)| \leq (1+\delta_p)$ for $0 \leq f \leq f_p$ and $-\delta_s \leq |H(f)| \leq \delta_s$ for $f_s \leq f \leq 1/2$ (Figure 1) can be estimated as

$$N \approx \frac{-20 \log_{10}(\sqrt{\delta_p \delta_s}) - 13}{14.6(f_s - f_p)} \quad (2)$$

After estimating N for a set of specifications f_p , f_s , δ_p and δ_s , a direct design consists in finding the values $h(k)$, with $0 \leq k \leq N$, that make the filter to accomplish the desired specifications. This is usually done with the Parks McClellan algorithm (Taylor, 2012).

Figure 3. Direct-form implementation structure of an N -th order symmetric filter, with N even

From the above estimate, it is seen that as the transition bandwidth $f_s - f_p$ is made smaller, the filter order N increases inversely proportional to it. Therefore, the direct design method yields very costly filters in applications where the transition bandwidth is narrow. For these applications, specialized design methods must be employed.

EFFICIENT METHODS TO DESIGN FIR FILTERS WITH NARROW TRANSITION BANDS

A filter having every one of its delay elements replaced by M delays is called a filter expanded by M (M is a positive integer greater than 1). Expanding a filter by M is equivalent to introduce $M-1$ impulse response coefficients with value zero between each of its coefficients. Its frequency response is periodic over f with period given as $1/M$, where M is the expansion factor, and an expanded filter is so-called a periodic filter.

In the following we provide a review of some popular methods to design low-complexity linear-phase FIR filters having the specifications illustrated in Figure 1. All the methods are explained for the usual case of low-pass filters.

Interpolated Finite Impulse Response (IFIR) and Generalized IFIR methods

The Interpolated Finite Impulse Response (IFIR) method is considered pioneering in the use of periodic subfilters (Milic, 2009). This method uses two subfilters: a model filter and an interpolator filter. Their respective orders are N_m and N_i . Thus, the computational complexity of the IFIR filter is approximately $(N_m + N_i)/2$ multiplications and $N_m + N_i$ additions. The model filter is expanded by a factor M and generates the shape of the desired frequency response with (approximately) M times less complexity than a direct design. However, it introduces unwanted images of that frequency response in the interval $0 < f < 1/2$. The interpolator filter is cascaded to the model filter to remove these unwanted images. To take advantage of the IFIR method, the value M must guarantee that $(N_m + N_i) < N$ holds. The optimum value of M is approximately $1/[f_p + f_s + (f_s - f_p)^{1/2}]$ (Mehrnia & Wilson, 2004).

The generalized IFIR method (Mehrnia & Wilson, 2004) consists in applying the IFIR method to design the interpolator filter of an IFIR filter. The IFIR method is used again to design the resulting interpolator filter, and so on. The process is repeated K times in total. The final filter, called generalized IFIR filter, has $K+1$ model filters, expanded by the values $M_1, M_2, \dots, M_{K+1}$, cascaded with an interpolator. The orders of the model filters are $N_{m,1}, N_{m,2}, \dots, N_{m,K+1}$, and the order of the interpolator filter is N_i .

The value of K is usually found by exhaustive search, i.e., K is set equal to 1 and the resulting generalized IFIR filter is compared with an IFIR filter (where $K = 0$). If the generalized IFIR filter uses a lower number of arithmetic operations than its IFIR counterpart, K is increased by 1 and the result is compared with the generalized IFIR filter designed using the previous K . The value K keeps increasing by one while the computational complexity of the current design is less than that of the previous design. When the aforementioned

condition no longer holds, the resulting generalized IFIR filter is the one designed in the previous iteration. For a given K , the values $M_1, M_2, \dots, M_{K+1}$ are those that minimize the number of arithmetic operations in the overall filter. Figure 4 shows the structure of a generalized IFIR filter, where $h_{m,k}(n)$ represents the impulse response of the k -th model filter, and $h_i(n)$ represents the impulse response of the interpolator filter. Note that, if only a single model filter is used, the structure corresponds to a traditional IFIR filter.

Frequency Response Masking (FRM)

Let us consider a linear-phase FIR filter that has an impulse response $h(n)$, with $0 \leq n \leq N$, and an even order N , i.e., $N = 2l$ with l integer. Its complementary filter is another filter whose impulse response is $h_c(n) = 1 - h(n)$ for $n = l$ and $h_c(n) = -h(n)$ for other values of n that satisfy $0 \leq n \leq N$. The complementary filter passes the frequencies that its counterpart rejects with a passband deviation being the stopband deviation of its counterpart and vice versa (Milic, 2009).

A filter designed with the Frequency Response Masking (FRM) FRM method is called FRM filter. In the FRM method two filters are created: the filter F1 and the filter F2. F1 is formed by con-

Figure 4. Structure of a Generalized IFIR filter

necting in cascade a filter expanded by M , called expanded model filter, with a masking filter, called masking- m filter, which passes some of the frequency response images of the expanded model filter. The filter F2 is formed by connecting in cascade the complementary filter of the expanded model filter with another masking filter, called masking- c filter, which passes some of the frequency response images of the complementary filter. The filters F1 and F2 share the same input and their outputs are added to form the output of the overall FRM filter. Since knowing the impulse response of the model filter allows knowing the impulse response of its complementary counterpart, only three filters need to be designed in the FRM method: the model filter with impulse response $h_m(n)$ and order N_m (which must be even), its masking filter (masking- m filter) with impulse response $g_m(n)$ and order N_{Gm} and the masking filter of its complementary counterpart (masking- c filter), with impulse response $g_c(n)$ and order N_{Gc} . Figure 5 shows the structure of a FRM filter, where $D_1 = MN_m/2$ and $D_2 = |N_{Gm} - N_{Gc}|/2$. The structure in Figure 5(a) is chosen when $N_{Gc} > N_{Gm}$, otherwise we choose the structure in Figure 5(b).

The value M must guarantee that the sum $N_m + N_{Gm} + N_{Gc}$ is less than N , such that the computational complexity of the FRM filter results lower than the computational complexity of a directly

designed filter. The optimum value of M is near to $0.5[1/(f_s - f_p)]^{1/2}$.

Serial FRM

Much effort has been made to improve the FRM filter structure. One of the most successful methods was presented by (Wei & Lian, 2010), where the use of serial masking schemes was proposed. The insight of this approach is that the expanded model filter and its complementary counterpart do not need to use their own independent masking filters. Similar to the FRM method, three filters need to be designed: the model filter with impulse response $h_m(n)$ and order N_m and two masking filters, called masking-1 and masking-2 filters, whose impulse responses are, respectively, $g_1(n)$ and $g_2(n)$, and whose orders are, respectively, N_{G1} and N_{G2} . The orders N_m , N_{G1} and N_{G2} must be even.

The expanded model filter is first cascaded with the masking-1 filter expanded by an integer L . Then, the output of this connection is added with the delayed output of the complementary filter and finally the output of this addition is cascaded with the masking-2 filter. With this, a lower computational complexity is obtained in comparison to the traditional FRM method because the expanded masking-1 filter has few non-zero coefficients. Since in the resulting structure both

Figure 5. Structure of a FRM filter

Figure 6. Structure of a Serial FRM filter

masking filters are serially connected, the scheme is called Serial FRM. A filter designed with this method is called serial FRM filter. Figure 6 shows the structures of serial FRM filters for these cases, where $D_{G1} = LN_{G1}/2$, $D_3 = LN_{G1}/2 + N_{G2}/2$. There are four design cases in the serial FRM method. Any structure in Figures 5(a) or 5(b) is used for $f_s < 1/4$. Otherwise, any structure in Figures 5(c) or 5(d) is employed.

 Figure 7. Structure of a Two-stage FRM filter with non-periodic frequency responses ($N_{Gm} > N_{Gc}$ is assumed)

Two-Stage FRM with Non-Periodic Frequency Responses

For cases with very narrow transition bands, designing the expanded model filter of an FRM filter as another FRM filter results in a convenient option. The method recently introduced by (Wei & Liu, 2013) and (Wei, Shaoguang & Ma, 2015) uses that approach.

Similar to the FRM method, the following subfilters are used: the model filter and its complementary counterpart, as well as the masking- m filter, with impulse response $g_m(n)$ and order N_{Gm} , and the masking- c filter, with impulse response $g_c(n)$ and order N_{Gc} . Nevertheless, here the model filter is composed by the following internal subfilters: a model filter expanded by M , its corresponding masking filter expanded by P , and the masking filter of the complementary model expanded by Q . By tuning the integers M , P and Q , an overall low-complexity design can be achieved. Figure 7 shows the structure previously described. The delays D_1 , D_2 and D_3 are obtained in a similar way as explained in the previous section. The name non-periodic is because the external model filter has a non-periodic frequency response.

Advantages of IFIR- and FRM-Based Filters

The advantages of an IFIR- or FRM-based filter in comparison to a directly designed filter are the following:

- The number of adders and multipliers required in the IFIR-/FRM-based filter is less than the number of adders and multipliers required by the directly designed filter.
- Since the computational complexity of the IFIR-/FRM-based filter is less than the computational complexity of the directly designed filter, the former has a lower power consumption.

The price to pay for these advantages is an increase in the number of required delay elements.

Simple Design Guidelines

Even though the decision of using either IFIR-based or FRM-based methods for a given design specification is not straightforward, in the following we present simple guidelines to make easier such choice.

- The IFIR-based methods are suitable for filters with narrow passband, i.e., where $f_s < 1/4$. However, if a filter with wide passband is required, a useful IFIR-based solution consists in designing the complementary counterpart of the desired filter. Then, the complementary version of the designed filter is implemented.
- A region of usefulness of the IFIR method in a plane of band-edge frequencies is presented in Figure 8. R1 is the region for low-pass filters with narrow passband, R2 is for high-pass filters with narrow passband, R3 is for high-pass filters with wide passband and R4 is for low-pass filters with wide passband. If the desired band-edge frequencies of a given filter lie into the re-

gion of usefulness, it is expected that the IFIR method provides a low-complexity solution.

- The FRM method was proven in (Wei & Liu, 2013) to be effective when the transition band of the desired filter, $f_s - f_p$, is less than $1/16$. Moreover, the FRM method is expected to be more effective than the IFIR method “if the square root of the normalized transition bandwidth is less than the arithmetic mean of the normalized passband edge and stopband edge” (Wei & Liu, 2013, pp.3270). In general, FRM-based methods should be applied when the band-edge frequencies do not lie into the region of usefulness of the IFIR method.
- For cases where $f_s = 1/2 - f_p$, neither the IFIR-based methods nor the Serial FRM method can be used. In this case, the traditional FRM method is better. If the passband and stopband deviations are equal, i.e., $\delta_p = \delta_s$, the method presented by (Lim, Yu & Saramaki, 2005) is particularly useful.

FUTURE RESEARCH DIRECTIONS

The efficient design of digital FIR filters is closely related to the emerging DSP technologies and applications. The hitherto methods are not capable of completely satisfying the plethora of conflicting design requirements like stringent design specifications, low power consumption, high speed of computations and low time and design effort, just to name a few. Therefore, it is important to pursue research towards more general methods to design low-complexity FIR filters, where subfilter-based techniques can be appropriately improved and then applied in a holistic point of view depending on the required application and the implementation platform. However, this task must be delimited taking into account the evolving technologies and their capacities, as well as the priorities in the design goals.

Figure 8. Region of usefulness in terms of band-edge frequencies for IFIR-based filters

Designs based on periodic subfilters can be effectively used, depending on the frequency response specifications, the clock rate available and the metrics for area, speed and power efficiency in different target technologies. However, keeping separated design methods for distinct applications and gradually migrating to most general methods whenever is possible is a wise decision. In this sense, the emerging design of sparse filters (filters where the number of non-zero coefficients is minimized, subject to a desired magnitude response specification) can be also investigated.

Recently, Field Programmable Gate Array (FPGA) platforms have gained a tremendous ground in the field of DSP and therefore this can be the target technology for future research. The current FPGA technologies include a much wider number of dedicated DSP resources that can be efficiently used for schemes based in periodic subfilters. The efficient integration of these resources to design low-complexity FIR filters with increasingly strict frequency response specifications is also an important research to be carried out.

CONCLUSION

In this chapter we have introduced the concept of digital filter as a system that modifies the characteristics of discrete-time signals. Particularly, Linear Time-Invariant (LTI) filters with Finite Impulse Response (FIR) characteristic have been addressed because of their advantages, namely, guaranteed stability and feasibility to be designed with linear phase. We have presented the characteristics of the impulse response of a FIR filter with linear phase, and it has been shown how to estimate the order of a linear-phase filter from its specifications of band-edge frequencies and passband/stopband magnitude deviations.

The main focus of this chapter has been the efficient design of linear-phase FIR filters. Since FIR filters with narrow transition band have a high computational complexity when they are implemented in direct-form, we have presented some of the most efficient methods to design linear-phase FIR filters with narrow transition band and low computational complexity. These methods are based on the use of periodic subfil-

ters. Particularly, the Interpolated Finite Impulse Response (IFIR) method and its generalized version, as well as the Frequency Response Masking (FRM) method and its recent modifications, have been concisely explained.

The end of the chapter presents simple guidelines to decide whether using IFIR-based or FRM-based methods for a given set of band-edge frequencies. Additionally, future research directions on the design of low-complexity FIR filters have been highlighted. Even though the set of existing methods for efficient design of FIR filters is vast, the present chapter offers a solid reference that explores two of the most useful methods to design low-complexity linear-phase FIR filters.

KEY TERMS AND DEFINITIONS

Adder: A component of a digital filter that produces at its output the sum of the values of the samples present at its inputs.

Complex Exponential Signal: A signal whose samples are complex numbers, where the real and imaginary parts of the samples form, respectively, a cosine wave and a sine wave, both with the same frequency.

Complex Function: A function whose values are complex numbers.

Complex Number: A number composed by the sum of a real number a and an imaginary number $i \times b$, where b is a real number and i is defined as the square root of -1 .

Delay: A component of a digital filter that has one input and one output. The delay retains its input value during a sampling period T_s and releases it at the next sampling interval.

Lineal Time-Invariant (LTI): Let us consider a filter that has as input a scaled sum of arbitrary discrete-time signals. If the output of this filter is equal to the scaled sum of the outputs of the filter to every one of these arbitrary signals, the filter is considered linear. If additionally the input signal is delayed in any possible amount and the output signal undergoes the same delay as the input, the filter is also considered time-invariant. A filter is LTI if it has both, linear and time-invariant properties.

Magnitude Response: A function of the frequency f where every value is obtained as the magnitude of the complex value of the frequency response in that frequency f . If the value of the frequency response in f is a complex number of the form $a(f) + i \times b(f)$, the magnitude of that number is given by $\{[a(f)]^2 + [b(f)]^2\}^{1/2}$.

Multiplier: A component of a digital filter that takes the samples at its inputs and produces the multiplication of these values at its output.

Phase Response: A function of the frequency f where every value is obtained as the phase of the complex value of the frequency response in that frequency f . If the value of the frequency response in f is a complex number of the form $a(f) + i \times b(f)$, the phase of that number is given by $\arctan\{b(f)/a(f)\}$.

Open Source

Heidi Lee Schnackenberg
SUNY Plattsburgh, USA

INTRODUCTION

Open source is a philosophy and a methodology associated with free and collaborative, creation, modification and use of software applications and operating systems. The term “open source” was coined in 1998 at the “Open Source Summit” in Palo Alto, California in an effort to standardize both the idea and a word or phrase for it. Shortly thereafter, the “Open Source Initiative” (OSI) was formed and sought to promote the idea of free applications (specifically, free source code) to the public (Tiemann, 2009).

Open source is characterized by a particular creation process associated with the development of software and/or operating systems. It is protected by specific licenses which allow users and developers the ability to freely modify, upgrade, use and distribute the products as they wish (von Krogh & Spaeth, 2007). Although not relegated to a hierarchical structure, a project manager generally emerges and leads the initiative by keeping things organized and moving forward while volunteers offer their talents by designing, coding, debugging, beta testing, and utilizing the product (Crowston & Howison, 2006). Volunteers can also offer feedback and provide technical support, either in-person, via phone, or in online user forums. This process can end in the free proliferation of an open source product, which users can modify and improve according to their specific needs. Although open source products can have imperfections, the user isn’t paying for those deficiencies like they sometimes do with commercial products (Schnackenberg & Vega, 2010). At times, open source products can also lead to a profitable venture if the software is sold to a company and marketed commercially. O’Neill

(2012) notes that open source can be viewed as a change agent. It has altered the way software and operating systems are produced and marketed, and has even modified the way knowledge is created. In this way, open source has also redefined business and marketing models around the world (Bonaccorsi, Giannageli, & Rossi, 2006; von Krogh & Spaeth, 2007).

BACKGROUND

An excellent example of this is the way in which open source has made deep inroads into the realm of mobile technologies (Chao, 2011). While “free” applications for mobile devices – smart phones, cell phones, tablets, etc. – are available for download, they are not open source products. These “free” applications, or “apps” are merely trial or limited versions of more complete products that users are tempted to buy in order to get the most complete functionality (Schnackenberg, Vega, & Heymann, 2014). True open source mobile applications come complete to the user when downloaded, and their source code is available for altering (Syer, Nagappan, Hassan, & Adams, 2013). In fact, the operating system of the Android smart phone itself is open source (Butler, 2011). Presently, the number of open source mobile applications (apps) available to download on smart phones that assist the user in completing day-to-day activities is growing exponentially. It is likely that smart phone, cell phone, and tablet users all search for free, open source, “apps” before they download the ones that are commercially produced. Given that, it is clear that open source has indeed impacted mobile technologies and will continue to do so for the foreseeable future.

DOI: 10.4018/978-1-5225-2255-3.ch543

In many senses, open source is a prevalent common practice of the hacker community (Sarma & Matheus, 2015; Soderberg & Delfanti, 2015), and a strongly held belief of technological idealists (Lakhani & Wolf, 2007). It is perhaps a type of high-tech grassroots movement. Open source products and applications are a manifestation of these practices and beliefs from which lay people can benefit. In his book, *The Cathedral and the Bazaar*, Raymond (2005) famously likens the culture and the creation process of open source to a bazaar, or an open market, where everyone has some unique goods to offer that all interplay for the benefit of the whole. Raymond contrasts this to the very hierarchical way in which ancient cathedrals were built. Despite its philosophical underpinnings and model of operations running entirely counter to conventional wisdom about how knowledge is created and how traditional business models function, the open source movement has taken a strong foothold in our technological culture (Weber, 2005).

Issues, Controversies, Problems

Several challenges with open source and open source products exist with varying degrees of frustration for developers and users (Meeker, 2008). The following is a description of some of the most prevalent issues with open source:

- **Confusing Licensure:** For the most part, OSS is free to modify for individual user needs. *Copyleft* is a term commonly associated with open source. It is a form of licensing that makes use of copyright law to ensure that a software, and its subsequent upgrades, can always be freely modified by users (van Holst, 2013). Different open source products, or different versions of open source products, can carry varying restrictions and usage policies. It is difficult to tell which software you can modify in what ways because there is no consistency in the licensing policies. At times, it

could be risky to utilize certain software in a particular way, or combine other software for a specific function, or to even create an entirely different product, for fear of violating licensing restrictions. To read all of the varying agreement policies that a developer or group of developers can attach to open source software can be extremely time-consuming and frustrating;

- **Collaborative Creation Process Doesn't Necessarily Mean That the Product Will Be Better:** One of the great attractions of the open source movement is that products can be modified by a developer or group of developers (Tapscott & Williams, 2006). The idea of software creation being a community process is novel to the computer application industry. While most commercially produced software is highly propriety and the source code and creation process quite secretive, open source products are a highly collaborate event. Admittedly, the idea of making software free and open to the public is an enormous, and attractive, economic and philosophical shift. However, sometimes too many individuals on a project can make the process inefficient and the product inferior. This phenomena is commonly referred to as "Brook's Law" (Brooks, 1886) and is particularly applicable when it comes to working on source code. Computer coding is a very detail-oriented, careful skill and often if one programmer makes an error when coding, it is difficult for another programmer to find and fix it. In this way, a piece of software can become either unfriendly to use or at worst, dysfunctional. Indeed, sometimes adding more software developers to a project doesn't necessarily make the product better;
- **Open Source Products Are Complicated to Use:** Linux-based products were originally designed for people who understand the concept of what makes Linux work.

The purest form of Linux requires a solid understanding of computer programming. One of the reasons for this is that by using what is known as typed “command lines,” a user can gain direct access to a particular application without having to wait to locate the application, then for the “pretty” graphics to reveal the application, and finally for the application to open in order to work. For many people who are accustomed to working in Windows or Apple environments, the idea of having to type a command that will open even a simple word processing application doesn’t seem worth the trouble (especially since the user would need to troubleshoot his/her command if an error is encountered). Therefore, the Graphical User Interface, or GUI, is vital in winning over users of traditional operating systems. Currently, more and more Linux-based operating systems now have GUIs for those who want to try Linux without the fear of the “command line” and allow users to simply point-and-click in order to access any application;

- **Similarly, Open Source Products Can Often Be Difficult to Install:** This is because, unlike commercial products, users are given options as to where to install software or operating systems. Open source applications can be installed in a variety of places on a computer’s hard drive, an external hard drive, or even on a jump drive or small USB drive. Conversely, commercial software simply leads the user through a pre-determined set of directions where s/he simply needs to accept where the applications are being installed. Granted, there are some choices as to where to install commercial software on a computer, but these are fairly limited. However, many users prefer the easiest method of software installation and for some, this means the least amount of choices and decisions possible;
- **A Final Factor That Can Add to the Complexity of Using Open Source Products is That Not All Software Runs on Open Source Operating Systems:** Running a GNU/Linux-based operating system requires users to understand that the commercial or proprietary applications that would normally run on Windows or Apple operating systems will not always run on GNU/Linux. Some applications are simply not compatible with others and it may take some trial-and-error to find out which programs work with which operating systems. While this sort of investigation may seem adventurous to some users, to others it would feel frustrating and inefficient. (N.B. There is, in fact, a way to enable Windows applications to run on GNU/Linux operating systems, but the process is extremely complicated and not for the faint of heart);
- **No Formal Help/Support and Poor Documentation:** Perhaps the least attractive aspect of using open source products is the fact that there is no formal support or help if the user has technical or usability problems. With proprietary products, manuals virtually always accompany them and often a helpline is accessible for specific hours each day. Interestingly, the open source community has responded to this by creating open, online, user groups, forums, and even videos on how to use, modify, and/or repair open source software. While the price is clearly right, corporations may often use commercial products because they are promised 24-7 technical support, free upgrades (for a specified time period), or they are given the software with the purchase of hardware. These perks certainly make the use of commercially-produced software attractive, particularly the promise of consistent technical support. Fortunately, open-source applications have come a long way. Many of today’s open-source products have associated technical

support in some capacity, sustained by the open-source community. Therefore, when a user looks up tutorials on how to use a specific application, a long list of individualized sites that can satisfy a variety of needs will usually appear. Still, this more prevalent appearance of technical support for open source may not be enough for the business community, where time means money and answers need to be obtained yesterday.

SOLUTIONS AND RECOMMENDATIONS

Despite facing some significant challenges, the open source movement has made strides to improve or correct the problems that it faces. Organizations like Creative Commons (2015) have provided a standardized way for its members to share their innovations through user-friendly copyright licenses. Its staff and volunteers assist users with tools for attaching the licensures to their work so that it can be shared, modified and utilized in the spirit of the open source initiative. Groups like Creative Commons have recognized and responded the confusing copyright issues that can accompany open source so that more people can customize and use the products without frustration or worry.

Similarly, many researchers (Bonaccorsi, Giannageli, & Rossi, 2006; Casadesus-Masanell & Llanes, 2011; Crowston & Howison, 2006) have studied how the collaborative process occurs in open source development. As noted, often, “too many cooks in the kitchen” can create an open source product that is ineffective. The same phenomena can also create an inefficient process, despite the quality of the product. The open source community has recognized that global collaboration may not always be the best approach for software development and several solutions to the problem have been suggested and implemented. Most notably, some structure or framework has

begun exist when a project is proposed and source code is made public. Project managers are often attached to the task and provide some organization for the work process. Alternately, a mixed model approach is adopted where some segments of commercial software development are adopted and a somewhat hierarchical structure exists. Another aspect of the collaborative process may be that developers already working on a project reserve the right to invite others to participate or deny some that right. Regardless of the approach taken to the shared -development model with open source undertakings, in most cases, some sort of organizational structure has begun to exist.

FUTURE RESEARCH DIRECTIONS

Although a significant amount of research has been done on open source since its inception (Raasch, Lee, Spaeth, & Herstatt, 2013), there are still many aspects of the movement and its associated initiatives that have yet to be investigated. For instance, the fact that free software and free operating systems are so readily available, yet consumers still prefer to pay for commercial products (which may or may not be better), is still intriguing. Commercial products are often released with well-noted errors and problems, similar to open source applications, yet the public still prefers to purchase this merchandise when they can acquire something of similar quality for free. This phenomenon is particularly puzzling and would be an interesting area of research to pursue.

Another aspect of open source worth investigating is how individuals come to be informed about the products and applications. A notable problem with open source is its lack of notoriety. How the public finds out about open source would be valuable information that could aid in its proliferation and adoption. It would therefore be beneficial to the open source community to find out how the public comes to know about its initiatives.

Social networks and open source is a new area also worthy of future study. While the so-

cial structures and norms of working within the open community and/or an open source project have been investigated to some extent, the use of open applications for what we more commonly think of as social networking has not yet been examined. Sites such as Facebook, Instagram, Snapchat, etc. are very prevalently used by many people, and accounts are free, but the code is not open for users to modify. These websites are also for-profit, despite the fact that they are free to use (for the most part) for patrons. It would be intriguing to explore what would happen if these social networking sites opened their source codes and allowed users to modify them according to their own needs.

Finally, it might be interesting for the open source community to do some predictive research and look to the future to see where technological innovation is headed and where open source applications might be most useful and/or popular. Intriguingly, when the author first began writing about the open source movement, mobile technologies were in their infancy. Who could have (or should have) predicted that open source applications for cell phones, smart phones, tablets, etc., would be where open source would have its strongest foothold in present day? It may benefit the open source community to do some forward thinking and perhaps anticipate this kind of opportunity in the future.

CONCLUSION

Open source has, in one form or another, permeated almost every aspect of modern technologies. Particularly with the advent and proliferation of mobile technologies, and the corresponding free “apps” needed to make them usable, open source has firmly rooted itself in the present day functioning of global citizens. Free source code, enabling programmers to modify a product to specifically suit their needs, is an enduringly attractive phenomenon. The coordination of a group

of programmers working on the same application can be challenging, especially when there is no formal hierarchical structure, but that may also be part of the allure of open source. Although commercially produced software is still the popular choice for most of the public, open source is a stalwart second place and rapidly gaining traction. Whether becoming part of the movement, or simply remaining a spectator, the open source movement is certainly one to observe closely in years to come.

KEY TERMS AND DEFINITIONS

Open Source: A philosophy and a methodology associated with free and collaborative, creation, modification and use of software applications and operating systems.

FOSS: Free Open Source Software.

FLOSS: Free and Legal Open Source Software.

Web 2.0: In the broadest sense, the second iteration of the World Wide Web (WWW), where web pages allow users to communicate, collaborate, and construct knowledge via social networks, video sharing sites, blogs, wikis, etc.

Intellectual Property: Ideas, creations, and inventions that are the exclusive property of the owners.

Linux: A Unix-compatible operating system that was collaboratively developed and is free to the public.

OLPC: One Laptop per Child.

Power Consumption in Wireless Access Networks

M**Vinod Kumar Mishra***B. T. Kumaon Institute of Technology, India***Pankaja Bisht***B. T. Kumaon Institute of Technology, India*

INTRODUCTION

Early wireless systems consisted of a base station with a high-power transmitter and served a large geographic area having less number of users. The systems were isolated from each other and only a few of them communicated with the public switched telephone networks. Today, the cellular systems consist of a cluster of base stations with low-power radio transmitters. Each base station serves a small cell within a large geographic area. The total number of users served is increased because of channel reuse and also larger frequency bandwidth. The cellular systems connected with each other via mobile switching center and directly access the public switched telephone networks. The most advertised advantage of wireless communication systems is that a mobile user can make a phone call anywhere and anytime.

The power consumption of ICT is approximately 4% of the annual energy production and it is expected that this number will double within the next 10 to 15 years. Internet traffic has a compound annual growth rate of 40%, which is an increase in two fold in every two years. The wireless world research forum (WWRF) has a vision of 7 trillion wireless devices serving 7 billion users by 2017 (Deruyck et al., (2011)). This indicates that the power consumption of wireless access networks become an important and crucial issue in the coming years. Earlier work also showed that the radio access network is a large contributor to CO₂ emissions. Particularly, the base stations

are responsible for roughly two-thirds of the CO₂ emissions of these radio access networks. NTT DoCoMo states that the daily energy consumption per customer is 0.83 Wh for a terminal and 120 Wh for the mobile network, which is a consumption ratio of terminal versus networks of about 1:150 (Jimaa et al., (2011)). The energy consumption of the terminals is thus negligible with respect to the energy consumption of the networks. Several studies indicate that within communication networks, the wireless access networks are high power consumers. Especially the base stations (BSs) are responsible for a significant part of the power consumption caused by wireless access networks. Therefore, it is clear that we should focus on the base stations in the wireless access networks in order to reduce the power consumption.

This chapter provides an overview and comparison of the power consumption of some of existing technologies of wireless access network and suggests the optimum technology for a specific area on the basis of power consumption per covered area. The recent significant literature and some frontier of this area are also included in this chapter.

BACKGROUND

The power consumption and energy efficiency of telecommunications networks become more and more important. For wireless access networks, most studies focus on energy-efficient deploy-

ments of wireless access networks. These studies shows that the user try to reduce the number of base stations in the network by switching them off during periods of low traffic which is a very promising method for energy savings. These studies in combination with a realistic power consumption model for base stations will enable to quantify the actual power savings in the network.

Jain, (2007), presented a description of the different Path Loss models. He gathered information from various IEEE and ITU standards. In Deruyck et al. (2014), authors presented the power consumption model for macrocell and microcell base stations and energy efficiency of three different wireless technologies (mobile WiMAX, LTE, and HSPA) has been compared. In Alshami et al. (2011), authors presented a comprehensive study of frequency analysis for different path loss on mobile WIMAX. They

discussed and implemented Okumura, Hata, Cost-231, Ericsson, Erceg, Walfish, Ecc-33, Lee and the simplified free space path loss models. In Deruyck et al. (2011), authors calculated the power consumption of base stations for mobile WiMAX, fixed WiMAX, UMTS, HSPA, and LTE. They introduced a new metric, the power consumption per covered area PCarea and investigated the influence of MIMO. In Deruyck et al. (2012), they categorized the base stations as macrocell, microcell, and femtocell base stations and compared the power consumption for each base station. In Sharma et al. (2012), they presented the calculation of path loss, link budgets etc, which are in the part of wireless system designing. Arif et al. (2013), presented a hybrid deployment model of a LTE-femtocell for a residential suburban scenario. In their model they placed the femtocell in a fix grid to

Algorithm 1. To calculate the total power consumption

Input: For all the technology Coverage Range R, PCmax, Wireless Technology to be used, Path Loss Models, and Total Power to be returned Pel. Declare Variables Ptot, Nsector, Ntx and R.

Output: Total Power Consumption.

Step 1: Start.

Step 2: Ptot = Calculate Total Power (Pel, Tech).

Step 3: Ptot $\leftarrow$ Ptot*1000 // to convert Power in milliwatt.

Step 4: Calculate the coverage range (d, Tech, Model).

Step5: PCmax= Ptot / (PI*R*R) // calculate power consumption per covered area.

Step 6: Return PCmax;

Step 7: If Nsector $\leftarrow$ 1, Ntx $\leftarrow$ 1 // for SISO system.
// the values of Pproc, Pamp, Ptrans, Pairco, Pmicro, Prect are same for all the technologies.

Step 8: If Nsector $\leftarrow$ 3, Ntx $\leftarrow$ 2// For MIMO system
// the values of Pproc, Pamp, Ptrans, Pairco, Pmicro, Prect are different for all technologies.

Step 9:End if

// defined procedure Calculate Total Power (Pel, Tech) to calculate total power for all the technologies.

Step 10: Pcomm $\leftarrow$ Pmicro+Pairco

Step 11: Pel $\leftarrow$ Nsector *(Ntx * (Pamp + Ptrans) + Pproc + Prect)+Pcomm

Step 12: Return Pel;

Step 13: Stop

Algorithm 2. To Calculate total coverage range (R) and the path loss (PLmax)

Input: Total Coverage Range d, Wireless technology to be used Tech, Path loss Model, PathLoss to be returned PLmax, Wireless Technology Tech. Declare Variables path loss(PLmax), frequency(f), Height of base station(Hbs) and mobile station, distance(d0), speed of light(C), shadowing margin(S), Correction factor, mobile station antenna gain(Gms), Declare Link budget variables Fade margin (Fm), Interference margin(Im), Transmitter output power(Ptx), Transmitter antenna gain(Gtx), Receiver sensitivity(Rs), Effective isotropic radiated power(EIRP), Connector loss(Lc), Mobile station antenna gain(Gms), Body loss(Blm).

Output: Coverage Range and Path Loss(PLmax).

```

Step 1: Start
Step 2: PLmax ← CAL_PATHLOSS (PL, Tech)
Step 3: if Tech ← Technologies (MWiMAX, FWiMAX, UMTS, HSPA, LTE)
Step 4: Set frequency (f) for all technologies
Step 5: determine coverage range (d) for macrocell base station using following models.
if(Model = Erceg C)
Elseif(Model =HATA)
Elseif(Model = ERCEG A)
Elseif(Model=ERCEG-B)
Elseif(Model =COST-231)
Elseif(Model=W-I)
Elseif Model=ITU-R
Step 8: Return d;
Step 9: Set Link Budget Parameters Gms, Fm, Im, Ptx, Gtx and Rs for all technologies put value from link budget table
// calculate Receiver sensitivity, where KTB is thermal noise, NF is noise figure, SINR is signal to noise ratio and IM is interference margin.
Step 10: Rs ← KTB+NF+SINR+IM-3
// Calculate Effective Isotropic Radiated Power.
Step 11: EIRP ← Ptx - Lc + Gtx.
// define procedure CAL_PATHLOSS (PL,Tech) to Calculate Total PathLoss.
Step 12: PLmax ← EIRP - Rs - Blm - Im - Fm - LC + Gms.
Step 13: Return PLmax;
Step 14: Stop.

```

calculate path loss for each femtocell. In Ho et al. (2013), they proposed the Quality of Service (QoS) supporting video streaming system with minimum data service cost over heterogeneous wireless networks. They determined that, one of the critical problems is power consumption at the mobile devices due to limited battery capability.

Although some researchers calculated the total power consumption and coverage range for two or three technologies using only one or two PathLoss models, but this seems to be missing in the literature that the calculation and comparison of the power consumptions of most popular wireless technologies using dif-

ferent Path Loss models (Erceg Type A, B and C, HATA model, COST-231 model, WI model and ITU-R model) at one place. In this chapter, we will provide calculation and comparisons of the total power consumption of most popular wireless technologies using different Path Loss models with coverage Range and power consumption per covered area. E.g. Long Term Evolution (LTE), mobile WiMAX (Worldwide Interoperability for Microwave Access), Fixed WiMAX, UMTS (Universal mobile telecommunication standard), HSPA (High Speed Packet Access) for SISO system and LTE, Mobile WiMAX, HSPA for 2x2 MIMO system using different path loss models.

MAIN FOCUS

In this section we describe the methodology to calculate the total power consumption of the base stations and power consumption per covered area for different wireless technologies. For this we use following two algorithms: first for the calculation of total power consumption and second to calculate the path loss and coverage area.

Detailed Description to Calculate the Power Consumption of the Base Stations

Power Consumption of a Base Station

In a base station, we typically find several power consuming components. Fig.1, 2 and 3 gives an overview of these components. The area covered by one base station is called a cell. Each cell is further divided into a number of sectors. Each sector is covered by a sector antenna.

Power Consumption of a Macrocell Base Station

In macrocell base station block diagram as depicted in Figure 1 shows that a macrocell base station consists of six power-consuming components.

- **Rectifier:** Converts alternating current (AC) to direct current (DC), also known as the AC-DC converter.
- **Digital Signal Processing:** Is concerned with the conversion of the signal to a sequence of bits or symbols and the processing of these signals.
- **Transceiver:** Is responsible for transmitting and receiving the signals.
- **Power Amplifier:** Converts the DC input power into a significant radio-frequency (RF) signal.
- **Air Conditioning:** Regulates the temperature in the base station cabin.
- **Microwave Link:** Is responsible for the communication with the backhaul network

If we take the sum of all those components, we can determine the base station power consumption. However, in Figure 1, we see that some of the components are used multiple times. Each of the components of the base station has its own typical power consumption which is given in Table 1. The power consumption of the microwave link and the rectifier is assumed to be constant throughout time. The power consumption of the air conditioning is not influenced by the time but rather by the temperature inside and outside of the base station cabin. For the power amplifier, the maximum power consumption is indicated. The power consumption of the digital signal processing and transceiver are based on the confidential data retrieved from an operator. Important to remark is the results presented in this chapter depend on the values listed in Table 1.

Furthermore, the power consumption of the power amplifier is also dependent of the input power of the antenna P_{Tx} . The power consumption of the power amplifier is determined as follows:

$$P_{el/amp} = \frac{P_{Tx}}{n} \quad (1)$$

where n efficiency of the power amplifier is the ratio of RF output power $P_{out/amp}$ to the electrical input power $P_{el/amp}$ of the power amplifier :

Figure 1. Block diagram of the base station equipment (Deruyck et al. (2012))

$$n = \frac{P_{out} / \text{amp}}{P_{el} / \text{amp}} \quad (2)$$

Power Consumption of a Microcell Base Station

For the macrocell base station, mobile WiMAX and fixed WiMAX has a typical P_{Tx} of 35dBm while HSPA, UMTS and LTE have a P_{Tx} of 43 dBm. Once the power consumption of each component is known, the power consumption of macro cell base station P_{el}/macro (in Watt) can be calculated:

$$P_{el}/\text{macro} = n_{\text{sector}} * (n_{Tx} * (P_{el}/\text{amp} + P_{el}/\text{trans}) + P_{el}/\text{proc} + P_{el}/\text{rect}) + P_{el}/\text{micro} + P_{el}/\text{airco} \quad (3)$$

Where P_{el}/amp , P_{el}/trans , P_{el}/trans , P_{el}/proc , P_{el}/rect , P_{el}/micro , P_{el}/airco denotes the power consumptions (in Watt) of the power amplifier, the transceiver, the digital signal processing, the rectifier, the microwave link (if present), and the air conditioning respectively, N_{sector} is the no. of sectors, n_{Tx} is the number of transmitting antennas.

Figure 2 shows that the same components are used for a microcell base station as for a macrocell base station except the microwave. The microwave (backhauling) of a microcell base station is typically established through the overlaying macrocell base station. A microcell base station supports only one sector covered by one antenna. The power consumption of the components is shown in Table 1 and is similar to those for the macrocell base station except for the power amplifier and the air conditioning. As fewer devices are present in the base station's cabinet, a less powerful air conditioning with lower power consumption can be used. Note that the air conditioning is not always necessary in a microcell base station but, in this chapter we included air conditioning also. The power amplifier consumes also less than for the macrocell base station because the input power P_{Tx} of the antenna is 33dBm for all consider wireless technologies.

Figure 2. Block diagram of Microcell base station equipment (Deruyck et al. (2012))

Once the power consumption of each component is known, the power consumption of micro cell base station $P_{el}/micro$ (in Watt) can be calculated:

$$P_{el}/micro = P_{el}/amp + P_{el}/trans + P_{el}/proc + P_{el}/rect + P_{el}/airco \quad (4)$$

Where P_{el}/amp , $P_{el}/trans$, $P_{el}/trans$, $P_{el}/proc$, $P_{el}/rect$, $P_{el}/airco$ are denotes the power consumptions (in Watt) of the power amplifier, the transceiver, the digital signal processing, the rectifier and the air conditioning respectively.

Power Consumption of a Femtocell Base Station

The size of a femtocell base station is much smaller than that of a macrocell and microcell base station and is comparable to that of a Wi-Fi access point. Therefore, the power-consuming components are different from those of a macrocell and microcell base station as shown in Figure 3. The femtocell base station consists of a microprocessor, a FPGA (Field-Programmable Gate Array), a transceiver and a power amplifier. The microprocessor is

responsible for implementing and managing the standardized radio protocol stack and the baseband processing and also takes care of the communication with the backhaul network. The FPGA is responsible for a number of features such as data encryption, hardware authentication, etc. The power consumption of these components is also listed in Table 1.

Once the power consumption of each component is known, the power consumption of femto cell base station $P_{el}/femto$ (in Watt) can be calculated:

$$P_{el}/femto = P_{el}/mp + P_{el}/FPGA + P_{el}/amp + P_{el}/trans \quad (5)$$

Where P_{el}/mp , $P_{el}/FPGA$, $P_{el}/trans$, P_{el}/amp are the power consumptions (in Watt) of the microprocessor, FPGA, transceiver, and power amplifier respectively.

We compare the power consumption with available data and measurements. For a 3-sector macrocell base station with one antenna per sector, P_{el} of 1673W is found with eq. (1) for UMTS, HSPA and LTE and P_{el} of 1279W for mobile WiMAX and fixed WiMAX. P_{el} for a

Figure 3. Block diagram of Femtocell base station equipment (Deruyck et al. (2012))

1-sector microcell base station with one antenna is 376W is found with eq. (2) for UMTS, HSPA, LTE, mobile WiMAX and fixed WiMAX. P_{el} for a 1-sector femtocell base station with one antenna is 12W is found with eq. (3) for UMTS, HSPA, LTE, mobile WiMAX and fixed WiMAX.

Power consumption values of the base station equipments are given as in Table 1. These values are received from datasheets of various

manufactures of network equipment's and from standards.

Calculate the Path Loss and Coverage Range

In calculation of total power consumption as described above, we know that how to calculate the power consumption P_{el} of the base station. It

Table 1. Power consumption of the macrocell microcell and femtocell base station components for the technologies considered (mobile WiMAX, fixed WiMAX, UMTS, HSPA and LTE)

Equipment	Parameter	Power Consumption (Base Station)		
		Macrocell	Microcell	Femtocell
Digital signal processing	$P_{el}/proc$, P_{el}/mp , $P_{el}/fpga$	100W	100W	7.9W (Microprocessor +FPGA)
Power amplifier (SISO)	N	12.8%	-	-
	P_{el}/amp (max)	24.7W($PTx=35$ dBm) 156W($PTx=43$ dBm)	16.6W ($PTx=33$ dBm)	2.4W ($PTx=33$ dBm)
Power amplifier (MIMO)	N	11.5%	-	-
	$P_{el}/amp(max)$	10.4W	-	-
Transceiver	$P_{el}/trans$	100W	100W	1.8W
Rectifier	$P_{el}/rect$	100W	100W	-
Air conditioning	$P_{el}/airco$	225W	60W	-
Microwave link	$P_{el}/micro$	80W	-	-

is dependent on the wireless range R covered by each base station. Now we calculate the Effective Isotropic Radiated Power (EIRP), Receiver Sensitivity (RS) and range. To calculate all these values a link budget has to be determined before.

Link Budget- a link budget is the most important entity for system-level design of wireless systems. It's a "budget" similar to an accountant's budget: the sum of gains and losses in various parts of the system has to result in satisfactory performance (typically output SNR or BER). The link budget includes all gains (and losses) from baseband input to baseband output (Deruyck et al. (2011)). Since values are gains/losses it is more convenient to add values expressed in dB instead of multiplying and dividing. The basic quantities included in a link budget are: transmitter output power, transmit antenna gain, path loss, receive antenna gain, fade margin and interference margin

Some typical link budget elements such as: transmitter feed line losses, transmit antenna gain, receiver antenna gain are also use to calculate the coverage range.

Path Loss: The path loss is the ratio of the transmitted power to the received power of the signal [4]. It is the reduction in power density of an electromagnetic wave. It includes all of the possible elements of loss associated with interactions between the propagating wave and any objects between the transmitting and receiving antennas. To determine the maximum allowable path loss PL_{max} , These parameters are retrieved from specifications and are typical values proposed by the operators themselves. The typical values allow making a fair comparison between the considered technologies. With the help of Path Loss we can determine the cell ranges.

After calculating the path loss for multiple technologies, it is very difficult to determine which one is the most energy efficient: one technology could have higher power consumption but also have higher ranges; another one could have a smaller range but also have lower power consumption. Therefore, the power consumption per covered

area is defined to quantify the power consumption and efficiency for different technologies:

$$PC_{area} = \frac{P_{el}}{AR^2} \quad (6)$$

Here P_{el} the power consumption of the entire base station (in watt) and R the covered range (in meters).

Simulation and Result Analysis

We used an open source simulator LTE-SIM, which is an open source framework for simulating different wireless networks. It supports C++ as the basic programming language. In this simulation, we place the base station outdoor in a suburban environment for macrocell and microcell and for femtocell base stations are placed in indoor environment. For macrocell with a transmitting antenna height is considered as 30 m and for microcell it is 6 m. Further we defined two configurations for the outdoor base stations: A basic reference configuration and extended configuration. In the basic reference configuration, one receiving and one transmitting antenna is considered, i.e., a SISO (Single input Single output) system. In the extended configuration both the base station and the receiver have multiple antennas, i.e., a MIMO (Multiple input Multiple output) system. The basic reference configuration is supported by all the technologies and for all macrocell, microcell and femtocell base stations, and the extended configuration is supported only by mobile WiMAX, HSPA and LTE for macrocell base station. The frequencies used for the link budget calculations of the different technologies are as following: 2.5 GHz for mobile WiMAX, 3.5GHz for fixed WiMAX, 2.1GHz for UMTS and HSPA, and 2.6 GHz for LTE. For the femtocell we used frequency 3.5GHz for all considered technologies. We used Erceg C as a reference model in our whole comparisons. The following Table 2 presents the parameters we apply in the simulation.

Table 2. Simulation parameters

Parameter	Value
Area type	Suburban, hilly area, indoor office
Number of sectors nsector	3 for macrocell and 1 for microcell and femtocell
Height of base station hbs	30 m for macrocell, 6 m for microcell
Height of mobile station hms	1.5 m for macrocell and microcell
Path loss model	Erceg type C, type A, type B, HATA, COST-231, W-I model, ITU-R P.1238
Shadowing margin	13.2dB for macrocell, 12.8dB for microcell

Coverage Range through Erceg C Path loss Model

Table 3 shows the simulation results using Erceg type C Path loss model for Suburban area. This table also describes the comparison of the wireless technologies (mobile WiMAX, HSPA and LTE) for SISO and 2*2 MIMO for macrocell base station.

Coverage Range Through HATA Path Loss Model

Here we compare the power consumption of wireless base station for mobile WiMAX, Fixed WiMAX, HSPA, UMTS and LTE access networks

for 1*1 SISO systems, for 2*2 MIMO system considered technologies is mobile WiMAX, HSPA and LTE. We used Path loss model HATA for calculating the range and area type is Sub urban area and used macrocell base station.

Coverage Range Through COST-231 Path Loss Model

Here we used COST-231 model for calculating the range, we compare the power consumption of wireless base station for mobile WiMAX, Fixed WiMAX, HSPA, UMTS and LTE access networks for 1*1 SISO system, for 2*2 MIMO system considered technologies is mobile WiMAX, HSPA and LTE. We used Suburban area and macrocell base station. COST-231 model is modified version of HATA model.

Coverage Ranges through Erceg Type A Path Loss Model

For calculating the range for hilly area terrain with heavy tree density we used Erceg type A path loss model. We compare the power consumption of wireless base station for mobile WiMAX, Fixed WiMAX, HSPA, UMTS and LTE access networks for 1*1 SISO system, for 2*2 MIMO system considered technologies are mobile WiMAX, HSPA and LTE. We used Hilly area and macro cell base station.

Coverage Range through Erceg Type B Path Loss Model

For calculating the wireless range for hilly area terrain or flat terrain with heavy tree density we used Erceg type B path loss model. we compare the power consumption of wireless base station for mobile WiMAX, Fixed WiMAX, HSPA, UMTS and LTE access networks for 1*1 SISO system, for 2*2 MIMO system considered technologies is mobile WiMAX, HSPA and LTE.

Coverage Range through Walfish-Ikegami Model Path Loss

We used WI model for calculating the wireless range microcell base station, we compare the power consumption of wireless base station for mobile WiMAX, Fixed WiMAX, HSPA, UMTS and LTE access networks for 1*1 SISO system. We used Suburban area and microcell base station. In the simulation we used the following

data, i.e. number of sector is 1, and Transmitting antenna is SISO, considered area type suburban, base station is microcell and mobile station height 1.5 m, base station height 6 m, roof height is 2 m and number of floors is 3. For this microcell base station we calculate the total power consumption through equation (2).

Coverage Range through ITU-R P.1238 Path Loss Model

We used ITU-R model for calculating the wireless range in femtocell base station, we compare the power consumption of wireless base station for mobile WiMAX, Fixed WiMAX, HSPA, UMTS and LTE access networks for 1*1 SISO system. In the simulation we used the following data, i.e. number of sector is 1, and Transmitting antenna is SISO, considered area type indoor office, base station is femtocell and frequency is 3.5 GHz. For this femtocell base station we calculate the total power consumption through equation (3).

CURRENT AND FUTURE TRENDS

We considered only sub urban area while in the future the total power consumption can be calculated for rural and urban area and reader can also work on how to reduce the total power consumption for base stations?

CONCLUSION

This chapter described the total power consumption, coverage range and power consumption per covered area for the most popular wireless technologies and compared the power consumption of these technologies in the 5 MHz bandwidth for macrocell base station and area has considered as suburban type, if one input and one output (SISO) transmitting antenna is considered the result showed that UMTS is most energy efficient and its range is higher than other technologies and through HATA model UMTS gives higher range and less power consumption area. Fixed WiMAX is less energy efficient but its range is not high, LTE is more energy efficient than mobile WiMAX and its range are higher than mobile WiMAX, HSPA is less energy efficient. Furthermore the results of MIMO showed that Mobile WiMAX is most energy efficient than LTE and HSPA.

KEY TERMS AND DEFINITIONS

Effective Isotropic Radiated Power (EIRP):

It is the output power when a signal is concentrated into a smaller area by the antenna. It radiates power equally in all directions.

Enhanced Data Rates for Global Evolution

(EDGE): The enhanced data rate for global evolution (EDGE) is the new radio interface technology to boost network capacity and user data rates for GSM/GPRS networks. It has been standardized by ETSI and also in the United States as part of the IS-136 standards.

HSPA (High Speed Packet Access): The standard mainly designed to support high speed data rate in the uplink and downlink. HSPA falls under categories viz. HSDPA, HSUPA and HSPA+.

LTE Technology: A new network architecture, which is developed by the 3rd Generation Partnership Project (3GPP) and support radio access network (RAN). LTE constitutes the latest step towards the 4th generation (4G) of radio technologies designed to increase the capacity and speed of mobile communications.

Path Loss: The ratio of the transmitted power to the received power of the signal. It is the reduction in power density of an electromagnetic wave.

UMTS (Universal Mobile Telecommunication System): Developed by ETSI (European Telecommunications Standardization Institute) and operates in the 2.1 GHz band. UMTS uses W-CDMA (Wideband Code Division Multiple Access) as multiple access technique and has a maximum bit rate of only 3 Mbps. UMTS has been specified as an integrated solution for mobile voice and data.

Resource Management for Multimedia Services in Long Term Evaluation Networks

INTRODUCTION

Wireless multimedia networks are becoming progressively popular, which provide the mobile phone user to accommodate of access to information and services at any time, any place and in any configuration with user desire and due to demand of high speed internet and growing wireless multimedia communication systems, future communication systems are expected to transmit large amount of multimedia traffic such as video, voice and text with a variety of Quality of Service (QoS). The important issue for future communication systems and upto certain extend in current communication system is the time and frequency being used for scarce resources and the requirement of QoS for multimedia applications which are sensitive in nature. Long Term Evolution (LTE) is one of the fastest growing technology which supports a variety of applications like video conferencing, video streaming, VoIP, file transfer, web browsing etc. In order to support multiple applications, radio resource management (RRM) procedure is one of the key design that has a role in improving the system performance. Long Term Evolution (LTE) establishes a significant milestone in the evolution of 3G systems towards the fourth generation (4G) technologies. The expanding utilization of complex multimedia services requires an advanced resource management mechanism in particular in wireless network environment. The mechanism that is responsible

for managing and controlling radio resources are known as resource management. The admission control is one of the resource management mechanisms, and task of admission control is to admit or reject the establishment request for the new session.

The performance targets promised by LTE, make it an ideal solution to accommodate the ever increasing demand for wireless broadband. LTE's promised performance targets were made possible due to improvements such as implied system access architecture and a fully IP-based platform. LTE has also great enhancements in its enabling radio technologies by introducing orthogonal frequency division multiplexing (OFDM) and advanced antenna technologies (Astély et al., 2009). In addition, LTE capabilities are further improved with enhanced Quality of Service (QoS) support for multiple data services, such as voice and other multimedia applications.

The main challenges in 3G, 4G and in next generation cellular networks are maintaining the quality of service (QoS) requirements for each class of the multi-service traffic in the presence of the limited radio resources (Ghaderi & Bouataba, 2006). The components that are in-charge of over-seeing and controlling the radio resources are known as radio resource management (RRM). The procurement of wireless multimedia services to mobile users with a certain quality of service, force stringent necessities on the configuration of radio resource systems. Admission control for

wireless system has been generally concentrated on under distinctive system architectures and systems heads approaches.

In this chapter, we introduce the fundamental idea of the admission control design and quality of service (QoS) procurement in wireless and mobile network. Provide, in brief, the call admission control (CAC) mechanisms, under a radio resource management (RRM) to support multimedia applications in the next generation wireless cellular networks with different QoS requirements prerequisites e.g. transfer speed (bandwidth), delay/jitter, and priority. CAC schemes enable the system to provide QoS for the new and also for the existing calls. Resource reservation scheme, such as Guard Channel, is utilized to hold the resources for certain high priority calls. On the other hand, network is required to exploit the resource sharing among traffic to accomplish better channel utilization. Acquiring a right harmony between the two restricting criteria is again a huge challenge. This schemes cover RRM outline for the channel-based wireless system, such as the time division multiple access (TDMA) and the frequency division multiple access (FDMA) systems, as well as the interference-based code division multiple access (CDMA) system. We focus on the implementation of the admission control algorithm in the long term evolution (LTE) network which enhancing session establishment success. For this we use the concept of service degradation (also known as media degradation path (MDP)) for handling multimedia multiclass services in admission control. The next generation network will be supported via various service classes with different QoS. Each service class call will treated differently according to the set criteria and adopted operating principle for the admission procedure. Since multimedia service may contain several media flows and user preference regarding flow importance may also vary so “user” and “service” related knowledge can be used at session initiation to specify alternative service configuration. We apply this knowledge in the context of admission control in non-MDP algorithm. In this approach

the algorithm allows the sessions to be admitted with lower quality configurations, in cases when there are not enough resources to admitting optimal (highest quality) configurations. Algorithm is implementing on LTE Simulator (LTE-Sim) while previously this is implemented in other simulators. The result of simulation of this approach shows that by using this approach in existing algorithm the session admission probability will increase over non-MDP algorithm.

BACKGROUND

Numerous previous research works have been published that allow higher priority for handover calls over new calls. Most of these proposed schemes are in light of the thought of “guard band,” where various channels are reserved for the restrictive utilization of handover calls. Although schemes based on guard bands are simple and capable of reducing the dropping probability, these schemes also result in reduced bandwidth utilization. To improve resource utilization of the guard channel algorithm, Ramjee et al. (1997) proposed fractional guard channel algorithm. The fractional guard channel algorithm decides an acknowledgment or a dismissal of new calls with choice probabilistically changed as the quantity of occupied channels. In case that channel is sufficient available, handoff calls are accepted, but new calls can be rejected. In this way, in the fractional guard channel algorithm, dropping probability of handoff calls may be smaller than that of new calls. Ghaderi and Boutaba (2006) also introduced guard channel based schemes, in their scheme guard channel algorithm reserves some channels among the total number of channels for handoff and calls admission control procedure. Guard channel algorithm is straightforward and its implementation is simple. In addition, the guard channel algorithm may decrease the use of physical resources as the quantity of holding channels increments. Wang et al. (2003), Wu (2005) and Bae et al. (2009) have introduced Quality of service related admission

control schemes. Wang et al. (2003) introduced a probability-based adaptive algorithm for call admission control in wireless networks, and do a little examination. This is based on probability to control the guard channels as indicated by controlled QoS measure. Wu (2005) gave an overview of the issues and strategies in QoS provisioning for wireless networks, specifically, the study in five sub-areas, network service models, traffic specification, packet scheduling for wireless transmission, call admission control in wireless networks, and wireless channel characterization while Bae et al. (2009) have proposed resource estimated CAC algorithm. The quantities of PRBs which are allocated to the requested call are estimated in this algorithm. The type of the requested service and current MCS level of UE (user equipments) are needed for deciding the quantity of required PRB (physical resource block). What's more, the resource-estimated CAC algorithm calculates available PRBs in view of the PRB utilization of on-going call measured by eNodeB.

Many researchers have pointed out that call admission schemes enormously impact the network performances, and in the meantime a straightforward fixed call admission scheme will bring about low system efficiency without a doubt. Qian et al. (2009) have proposed a novel RAC scheme for multiclass services in LTE systems which go for improving system capacity while in the meantime ensuring QoS requirements of every service class. To upgrade the system capacity, they adopt a service degradation scheme if there should arise an occurrence of resource limitations in our RAC scheme. Shen and Li (2009) have developed the admission control algorithm for wireless mesh network (WMNs) in light of the estimation of the accessible bandwidth in MAC layer, which support the QoS in WMN. The Admission control algorithm treats various traffic types in different ways. It gives the real time flows with admission decisions at the MAC layer and the non real-time flows with sending rates. Kim et al. (2009) proposed Semi-Adaptive Call Admission Control (SA-CAC) approach which

joins resource allocation and CAC scheme. As per his work the bandwidth of an adaptive real-time call can just change during setup or handover occurrence. To maximize the network revenue and keep up predefined QoS requirements, the QoS limitations are classified as two categories: long period constraints and instantaneous constraints.

Antonopoulos and Verikoukis (2010) have introduced a connection admission control (CAC) mechanism for IEEE 802.16 broadband wireless access standard. The issue of "occupied hour" in communications traffic variation is considered in this algorithm which gives the basis for the bandwidth reservation concept. WiMax infrastructure is mostly considered in this with the goal that it can be adjusted for long term evolution (LTE). This mechanism provides higher priority to VoIP calls contrasted with different types of traffic in the network.

Khanjari et al. (2010), Wang and Qiu (2013) and Chwdhury et al. (2013) introduced admission control scheme which follows the degradation concept, Khanjari et al. (2010) proposed an adaptive Call Admission Control (CAC) scheme for multi-class service wireless cellular networks. The proposed scheme utilizes Fairness policies for resource reallocation and allocation which consider the mechanism of call bandwidth degradation and bandwidth upgradation by utilizing the complete sharing approach of the accessible bandwidth among every traffic class, the scheme additionally applies call preemption as indicated by the class of call priorities and call reactivation at whatever point the traffic conditions are allowed. Wang and Qiu (2013) introduced a multi-service call admission control technique for LTE femtocell network. This strategy considers multiple classes of services with different QoS requirement and different bandwidth requirement. Wang considered the Guard Channel as a dynamic proportion rather than a fixed amount of Physical Resource Blocks (PRBs). Chwdhury et al. (2013) proposed a scheme of degradation if there should be an occurrence of scarce capacity, i.e. at the point when the accessible bandwidth is low, the

scheme releases some bandwidth from effectively accepted non real-time calls, as to suit new and for handover calls. More bandwidth is released to support handover calls bring over new calls.

Kim et al. (2013) presented a mobility aware call admission control (MA-CAC) with a handoff queue. The vehicle mobility governs the admission control policies. To keep up high channel use, MA-CAC introduced stop and moving stage: at the stop stage a handoff priority scheme with the guard channel concept is utilized and then again at the moving stage no guard channel reserved for handoff users. Williams and Asuquo (2014) introduced an effective model that can decrease call blocking probability and enhance the quality of service (QoS) gave to mobile users. The proposed model computes the steady state probability and resource occupancy distribution, traffic distribution, intra-cell and inter-cell interferences from mobile users. Recently Badri et al. (2015), Sepänen et al. (2014), Ivesic et al. (2013) and Ivesic et al. (2014) gave admission control mechanism for adoptive multimedia services.

On the basis of literature review, we conclude that the researchers addressed particular schemes, models and ways to deal with how to manage and keep up the quality of services (QoS) requirements of different multimedia services. A few schemes have connected to keep up a bandwidth reservation for handover call and new call, call blocking probability, handover call dropping probability and channel utilization. We observed that there is a need of the particular way to admit more session without dropping the call and maintain the quality of service and user preference in view of the current era of services. The MDP based admission control algorithm used to accomplish the objective of upgrade the session establishment executing on LTE Simulator.

MAIN FOCUS

Amid the most recent decades the wireless communication network clients have been quickly

expanded alongside their interest for new sight and sound services. The requirement for higher speed communication is as opposed to the rare spectrum resource distributed for wireless system in universal international organization. In this way, a fit resource management (RRM) is crucial to designate the current system asset among uniting clients, taking into examination their needs and separate needs us to give them the obliged QoS. RRM usefulness plan to enhance framework execution by boost the general framework limit in the wireless system protecting in the meantime QoS attributes of versatile clients. The admission control is one of the radio resource management mechanisms. The key idea of admission control is to ensure the QoS of individual connection by appropriately managing the network resources. The admission decision is based on not only the available network resources, but also the QoS requirements for requesting and ongoing users. Hence decision should be taken to consider multiple parameters such as the network characteristics, the service type, user mobility and the network condition. Long Term Evolution technology displays an exceptionally difficult multiuser issue: Several user equipment's (UEs) in the same geographic region require high data rates in a limited bandwidth with low latency. Numerous access techniques permit UEs to share the accessible bandwidth by allocating to each UE a fraction of the total system resources. The strong motivation past the Admission control schemes for admitting the session is the improvement of system performance by increasing the spectral efficiency of the wireless interface and thus improving the system capacity. A Call Admission Control (CAC) is an algorithm of decision-making that provides QoS in the network by restricting access to the network resources (Ghaderi & Boutaba, 2006).

According to the requested call type, CAC decides to accept or block the new call according to the network resources availability. At the point, when there are not sufficient resources to guarantee the call quality or to keep the active calls QoS (services already accepted-established),

CAC blocks the new call. Otherwise, the call is accepted.

The Quality of Service (QoS) and Quality of Experience (QoE) aware admission control (AC) determines whether a new radio bearer should be granted or denied access based on if required QoS of the new radio bearer will be fulfilled while guaranteeing the required QoS of the in progress sessions. Ivesic et al. (2013) proposed a degradation concept of knowledge (known as MDP) for maximizing the number of admitted session and to optimize the system capacity, they adopt a service degradation scheme in case of resource limitations. A multimedia service joins two or more media components, such as audio, video, text, data, 2D/3D graphics, Within a single session, the media components may be consolidated in distinctive ways, and need not be dynamic in the meantime their number, and in addition properties and prerequisites regarding network resources normally change. Multimedia services as a rule comprise of different media flows, the number and properties of which may change over the span of a continuous session. At the point when a session is initiated, AC mechanisms are invoked to make an admission decision based on operator policy, resource availability, service type, and user priority. Providing QoS insurance to different applications is a critical target in outlining the next-generation wireless networks. Different applications can have extremely different QoS necessities as far as data rates, delay bounds, and delay bound violation probabilities, among others chooses whether a connection request should be accepted or rejected, in view of the asked for QoS and the network status.

QoS/QoE-Aware Admission Control (MDP Based)

The collection of multiple feasible configurations of giving service concept is applied to the admission control problem. QoS Class Identifier (QCI) ensures bearer traffic is allocated appropriate QoS. Different bearer traffic requires different

QoS and therefore different QCI values. QCI classifies the different types of bearers into different classes, with each class having appropriate QoS parameters for the traffic type. Examples of the QoS parameters include Guaranteed Bit Rate (GBR) or non-Guaranteed Bit Rate (non-GBR), Priority Handling, Packet Delay Budget and Packet Error Loss rate. The QCI is a scalar that is used within the access network (namely the eNodeB) as a reference to node specific parameters that control packet forwarding treatment (e.g., scheduling weight, admission thresholds and link-layer protocol configuration). Here we assume that three service categories, which are referred to as low, medium, high and divide the available resources into zones pertaining to these categories. High class belongs to real time service flow with constant bit rate (CBR) such as voice and video phone service, medium service class is belong to real time service flow with variable bit rate (VBR) such as interactive multimedia and video streaming, and low class is belong to Non –real flow with VBR or UBR (Unspecified Bit Rate) such as email, file transfer service. The first zone is available to all sessions, the second to low service handoff sessions and all medium and high service sessions, the third to medium handoff sessions and all high service sessions and the fourth to high service handoff sessions only, Besides the zones, we also define the zone critical border B_0 as a limit that, when crossed by resource consumption, instructs the admission control algorithm to admit sessions with suboptimal configurations, For the session i the end of the zone that it belongs to is denoted by T_i and the area between the limits B_0 and T_i is defined as a critical area. The resource consumption is spans from left to right (from T_0 to F , w here F marks the end of the area with occupied resources and the beginning of the area with free resources), so that free resources are on the right. For each session, the zone critical border is calculated as a predefined percentage of the resources from the regarding zone, and the limits for different suboptimal configurations are created by dividing

the critical area into n equal intervals, where n is the number of configurations.

Pseudo Code for MDP Based Admission Control Algorithm (Ivesic et al., 2013)

```

For all the flows do
{
Determine the zone and set critical
border limit of the zone
Admission Control (flow, Zone limit,
occupied Resources, Bandwidth)
{
Initialize  $n \leftarrow$  Size of flow
Initialize the critical border limit
of QoS configuration B0 in available
Zone
B0.resize (n, zone)
Combine the available resources to
configure in each zone
While (!config.empty())
{
Zone_t zone =config.begin() -->first
For (availResource_iter = availRe-
sources.begin(); availResource_iter
!= availResources.end(); availRe-
source_iter++)
{
Zone_t QCI =qci;
If (QCI< B0 [v] && available resource
→ rsc <qci)
Select optimal configuration
Else if (QCI< T1) then
Select alternative config
}
}
Assign session
Else if (available resource == NULL)
Reject session
Return;
}
}

```

To evaluate the effectiveness of the Admission Control Algorithm we use the LTE Simulator. We implement this admission control algorithm in LTE-Sim, which is an open-source framework for simulating LTE networks developed by Giuseppe Piro, Luigi Alfredo Grieco, Gennaro Boggia, Francesco Capozzi, and Pietro Camarda. LTE Sim tool provides discrete event simulation of user defined Network. LTE-Sim supports several aspects of LTE networks from the application layer down to the physical layer, such as single-cell and multi-cell environments (Pietro et al. 2011), QoS management, multi-users environment, user mobility, CQI feedback, handover procedures, and frequency reuse techniques. Fundamental network nodes like UE, eNB, MME and S-GW are modeled in LTE-Sim, with the supports of the trace-based, Voice over IP (VoIP), Constant Bit Rate (CBR), and infinite-buffer traffic generators at the application layer and the management of data radio bearers.

For comparison we used a non-MDP based admission control algorithm which does not consider the concept of alternative configuration according to services and if occupied resources in the optimal configuration zone are equal to the limit of zone then reject the session.

Configuration

For the simulation, a cell of 10 MHz bandwidth and 2 GHz carrier frequency are modeled. The cell is assumed to consist of 50 RBs and K users and the users are simulated within 1 km radius.

The serving eNodeB has a fixed location at the centre of the cell and controls all the available RBs. These RBs are to be shared by all users within the cell. At each TTI(Transmit time interval), RBs can be assigned to a user. While other simulation parameters are simulation duration: 10.2 s, number of cells: 1, cell radius: 1 km, bandwidth: 10 MHz, scheduler: EXP rule, frame structure: frequency-division duplex, user speed: 3 km/h. In case of session arrival time, the admission

control module is invoked and initial resources are allocated if the session is admitted. The Zone limits for zone 1, zone 2 and zone 3 have been set to 85%, 90% and 95% of the available resources respectively. The limit of B_o (critical border limit of QoE configuration) has been set to 65% of the available resources within the given zone.

Result and Analysis

The simulation result indicated that, in the Case of applying non MDP based admission control the number of active sessions are near by 45%, and in the case of applying MDP based admission control the numbers of active sessions are near by 54%. The active bearers are close to 75% in non MDP based admission control while in MDP based admission control the number of active bearers are near by 90%. Thus in case of QoS /QoE admission control algorithm the admitted session and active bearers enhanced in comparison to non MDP admission control algorithm.

CURRENT AND FUTURE TRENDS

With the quick development of wireless networks and incredible achievement of Internet multimedia applications, the future wireless networks are imagined that they will not simply give a higher data rate to the mobile users, additionally to serve different mobile terminals ranging from just-voice phone (dumb phone) to smart phone, and to support heterogeneous applications with different quality of service (QoS) requirements in terms of data rates, delay and packet loss. Nevertheless, providing QoS or QoE in wireless networks is a challenging task while following the transmission condition of wireless channel which is dynamically changes over time.

We take note of that a present barrier of the LTE-Sim tools is an absence of backing for mapping service flow to numerous QCIs. We will likewise run longer simulations in LTE-Sim and

test the calculations in distinctive network conditions. The proposed admission control scheme can be simulated for a wireless cellular network of many cells. Wherein, an extended representation of physical mobility can be applied using mobility prediction techniques.

CONCLUSION

In this chapter, we provide an overview of the call admission control (CAC) mechanisms under a radio resource management (RRM) to support multimedia applications in the next generation wireless cellular networks with different QoS requirements. Implemented and analyzed a multi-service QoS/QoE admission control scheme for LTE network on LTE- simulator. This scheme considered various classes of services with diverse QoS necessity. The admission control system works on a flow premise as opposed to on classes, when another flow is entering the eNodeB the management system must choose whether there is sufficient ability to completely sustain the flow. The simulation result indicates the normal increment in admitting session and the quantity of bearers is marginally diminished in a few occasions. The detail discussion of recent significant literature and some frontier of this area has also included in this chapter.

KEY TERMS AND DEFINITIONS

1G Technology: 1G refers to the first generation of wireless telephone technology; mobile telecommunications which was first introduced in 1980s and completed in early 1990s. It is based on analog system. It's Speed up to 2.4 kbps and Allows user to make voice calls in 1 country. AMPS

(Advance Mobile Phone System) were launched by the US & it was the 1G mobile systems.

2G Technology: 2G technology refers to the 2nd generation which is based on GSM. It was launched in Finland in the year 1991. 2G network use digital signals. Its data speed was up to 64kbps. Features Included in 2G technology is: It enables services such as text messages, picture messages and MMS (multimedia message). It provides better quality and capacity. 2G are the handsets we are using, with 2.5G having more capabilities.

3G Technology: 3G technology refer to third generation which was introduced in year 2000s. Data Transmission speed increased from 144kbps-2Mbps. It provide Superior voice quality and Good clarity in video conference E-mail, PDA, information surfing, on-line shopping / banking, games, etc. This was followed by 3.5G, 3G+ or turbo 3G enhancements based on the high-speed packet access (HSPA) family, allowing UMTS networks to have higher data transfer speeds and capacity.

4G Technology: The next generations of wireless technology that promises higher data rates and expanded multimedia services. Developed in 2010. Its Speed up to 100 Mbps. Provide any kind of service at any time as per user requirements, anywhere.

Radio Resource Management (RRM): The mechanisms that are responsible for managing and controlling radio resources are known as radio resource management (RRM).

Quality Of Service (QoS): QoS is characterized as “totality of characteristics of a telecommunications service that bear on its capacity to fulfill expressed and inferred needs of the user of the service.”

Quality of Experience (QoE): QoE is defined as “the general agreeableness of an application or service, as perceived subjectively by the end-user.

Resource Block (RB): A Resource Block (RB) is a time- and frequency resource that occupies 12 subcarriers ($12 \times 15 \text{ kHz} = 180 \text{ kHz}$) and one slot = 0.5 ms).

SMS & Civil Unrest

M

Innocent Chilwa

Covenant University OTA, Nigeria

INTRODUCTION

According to Epstein (e.d.) (2015), “the whole world is texting...” in virtually all communication contexts of human endeavor. And studies show that a high number of telecommunication users rely on the Short Message Service (SMS) or texting via Smartphone to send and receive messages on different topics related to the society (Ahn, 2011); politics (Shirky, 2011); education (Aziz et al, 2013); business (Torres & Conaway, 2014); and religion (Bell, 2006; Campbell, 2005; 2006a; Chilwa & Uba, 2015), among others. According to *Pew Research Center*, over 6 billion messages are sent everyday in the United States (*Forester.com*) and about 8.3 trillion text messages were sent globally in 2015 alone, which is almost 23 billion messages per day or almost 16 million messages per minute (*Portio Research*). On the average, 8 trillion text messages are sent every year world-wide (*Bloomberg*). With this amazing prevalence of texting in our daily living, it is clear that SMS plays a significant role in influencing behavior, which includes initiating; implementing and championing civil unrests (see Chilwa, 2016), which unfortunately have become part of our everyday experience.

This entry is an updated version of my previous paper published in the *Encyclopedia of Mobile Phone Behavior*, (vol.2) entitled “Text messaging in social protests,” published by IGI Global (pages 1024-1031, 2015), edited by Zheng Yan. The current version contains new information on texting behaviors of protesters at different socio-cultural and economic contexts. Hence, the literature section has been expanded to include latest research findings.

“Civil unrest” in the current study is broadly used to include all forms of civil disorder, especially those associated with or organized by social groups, trade unions, civil rights groups, occupy movements, or university students. This will include mass protests (violent or “peaceful”); social or political unrests, street demonstrations; sit-ins and occupy protests, or industrial actions and strikes. In “text messaging in social protests,” (2015), I highlighted the fact that protest behaviors vary depending on the social and political contexts, as well the motives and the degree of participation. Hence, there is a peaceful protest that involves mass protesters in a protest march. In this case, protesters generally carry placards with protest messages. Protesters also sometimes wear T-shirts with protest messages inscribed on them (see Chilwa & Ajiboye, 2016). Sometimes, some peaceful protests have turned violent, when protesters began to engage security agents in direct confrontations through open fights and other criminal activities such as vandalism of public property, looting and raping. In this case what started as “peace” protests and rallies have ended up resulting in loss of lives and property. In most cases, security agents have had to resort to the use of tear gas or water canon to disperse protesters. An example was the Ferguson unrest that involved peaceful protests and riots that began a day after the shooting of a black American teenager (Michael Brown) by a white police officer Darren Wilson on August 9, 2014 in Ferguson, Missouri. The riots led to the imposition of curfews in the area and the deployment of the riot squad to maintain order. The protests continued until November 24, 2014 after a grand jury did not indict police officer Wilson.

DOI: 10.4018/978-1-5225-2255-3.ch546

As highlighted above, protest behaviors also include industrial actions involving labour/trade unions, where members deliberately stay away from work. In some peculiar circumstances, hunger strikes have also been engaged by individual protesters or activists. Extreme cases have been the deliberate self-immolations of activists in protest of institutional injustice. An example is that of Mohamed Bouazizi, the Tunisian street vendor, who set himself ablaze on December 10, 2010 in protest of the confiscation of his goods, and constant harassment and humiliation by municipal council officials. His death triggered off the Tunisian revolution. Collective actions and social movements participating at the same time have been caused by the need to achieve change, or “revolution” that is believed to be desperately needed either gradually or immediately or spontaneously (see Chilwa, 2012). In recent times mass protests have enabled protesters to express their grievances over perceived deprivation, frustration, injustice or violation of fundamental human rights by governments or constituted authorities (Stekelenburg & Klandermans, 2010). The Ferguson riots for example raised questions and debates in the United States about the relationship between law enforcement officers and African Americans, the militarization of the police and the use of force doctrine in America.

BACKGROUND

The spread of social/political protests around the world has been attributed to the impact of new information and communication technologies (ICTs). People who are concerned about political events and developments in their countries are radically responding and mobilizing against oppressive regimes and systems and demanding for change (Smith 2010). According to Garret (2010) social media and ICTs such as *Twitter* and *Facebook* are currently changing the ways in which activists communicate, collaborate, and demonstrate. And text messaging has played im-

portant roles alongside these other social media, sometime earning government ban. Though these protests respond to very different socio-political and economic circumstances, they share the same social features (Gonzalez-Bailon et al, 2011).

Social movement theorists have established that during civil uprisings, the media become a site for the construction of meaning and a space for the discursive and symbolic contests (Gamson, 2004). The use of the new forms of ICTs, particularly, *Twitter*, *Facebook* and text messaging have been sites for framing contests and as mobilizing structures. Due to their anonymous and decentralized characteristics, these networks are hard to control by government authorities and rapidly emerging as primary tools in organizing protests especially among tech-savvy youths. These virtual networks are also able to disseminate injustice frames in the form of videos, cartoons, or slogans to local and international audiences (Sarfati, 2015).

Social media use in protests is a modern (new) development; this also suggests that research literature in this field is still emerging. Studies on social media roles in contemporary mass protests have centered on *Facebook* and *Twitter*, while mobile phone use has not been explicitly documented. However, before the current overwhelming popularity of *Facebook* and *Twitter* in the organization and implementation of offline protests, text messaging via Smartphones had been used to champion revolutionary actions (Hong, 2006). For instance, Ahrens (2001) had observed that cell-phone was used to coordinate the protest against the World Bank, by American University activists in 2000, and concluded that mobile phone is a weapon in the hands of the mobilizing people seeking social justice. Obadare (2005) also documented the GSM boycott in Nigeria in 2005 that forced mobile phone operators to “vigorously renew their commitment to corporate social responsibility” (p.24). In his study of “how texting helped fuel the anti-austerity protests roiling Europe,” from early 2015, Jacob Groshek, an assistant professor of emerging media in the Department of Communication, Boston University, outlines the success

Smartphone technology and texting in mobilizing protests across European union states (e.g. Brussels in Belgium where over 100,000 protesters took to the streets in early October, 2015 and the police had to deploy water cannon to disperse them). In Groshek's own words:

my research shows that one of the most basic forms of modern communication and simplest uses of a Smartphone, the text message, was crucial to mobilizing anti-austerity efforts across the European Union... What I found (using the regression modeling method) was that the volume of text messages sent in all countries was a positive predictor of protest activity, as were youth unemployment rates. What this means is that as the total number of text messages sent went up in one year, protest activity increased in the next year. The same was true for youth unemployment rates. More protests followed rising levels of joblessness among young people... (pages 1 & 2). The study focused on 24 European Union states.

The story of mobile phones in protest planning and implementation by activists ranges from the success of coordinated "flash mobbing" to "txtmobbing" and "swarming." A "flash mob" is defined in terms of a group of people brought together often by text messages or social media to a designated location at a particular time to perform an indicated action before dispersing; thus, texting and media technology enable flash mobbers/protesters to instantaneously communicate with one another and are empowered to immediately change venue such as train stations, parks, town squares, and in some cases challenge or evade authorities (Fitzpatrick, 2013). Similarly, a *TXMmob*, which was developed in collaboration with protest organizers, and has been applied by widespread adoption of SMS-enabled cell phones among activists and by evolutions in protest tactics, facilitated new social formations and modes of participation (Hirsch & Henry, 2005:1455). Texting has also been instrumental for coordinating "smart mobs" (Rheingold, 2002) or swarming.

The latter, which is recognized as a tactic of mobilizing actions by decentralized groups, is used in military parlance to describe a "dispersion of command among many small, autonomous units that are able to collectively attack an enemy from all directions" (Hirsch & Henry, *ibid*). This method was used to describe the June 18 (J18) actions that occurred around the world, which also paralyzed central London in 1999, as well as the demonstrations that shut down a World Trade Organization (WTO) meeting in Seattle in the same year (see Hirsch & Henry, 2005). Text messaging appeared as an ideal medium to coordinate these types of protests since cell phones are common and users would not immediately be identified as members of protest movements. Widespread cell phone use also meant that the protest networks could be expanded by thousands of activities without requiring the purchase of expensive radio technology. SMS is a technology that is widely adopted by many social sectors and relies on vibrant networks that are controlled by large companies (*ibid*).

In addition to texting, few studies have documented the use of Blackberry Instant Messaging (an extended system of mobile phone technology) in protests. Reporting the north London riots of 2011, Halliday (2011) notes that Blackberry handsets was used by about 37% of British teenagers. Blackberry Messenger (BBM) enables users to send one-to-many messages to their network contacts, who are connected by "BBMPINS." Unlike Facebook or Twitter, many BBM messages are not traceable by the authorities making BBM the most preferable by teens to spread gossip and mobilize for civil unrests. In the London protests for example, protesters had first gathered on Facebook with more than 7,500 fans to mourn and vow to avenge the murder of a Tottenham resident (Mark Duggan) and by 10.30 pm on Saturday (August 6), protesters had thronged the Tottenham High Road in a first public show of protest; this turned into a full blown uprising with widespread rioting and looting. Sheid (2013) further adds that BBM allows users to send free messages to individuals and to all their contacts simultaneously; the

belief remained that individuals were using the BlackBerry as a tool for coordinating activity, allowing rioters and looters to stay one step ahead of the police. This had warranted the call for the suspension of BBM by a Member of Parliament for Tottenham who identified BBM as “the reason that criminals were outfoxing the police force, noting that encryption prevented access for the police” (p.176).

OFFICIAL RESPONSES TO SMS IN SOCIAL PROTESTS

Recognizing the importance of information sharing during protests and the danger inherent in some actions considered as unlawful, some governments, the police and security agents have attempted to disrupt communication networks by interfering with activist mobile technology based media and by arresting activist group members. Two men, for instance, were arrested and charged for sending mobile text messages and using social media sites to recruit people for “violent” demonstrations in Sidney in September, 2012. The man was accused of planning an anti-Islamic protest and had sent texts and online messages to incite members of the public to participate in a Sidney protest and commit acts of violence (Ralston, 2012). Chittum (2013) similarly reports the case of the “temporal” interruption of mobile wireless service at train stations in San Francisco in 2011 by the Bay Area Rapid Transit (BART) after they suspected a flash mob protest following the killing of a man by the BART police. The action was intended to prevent protesters from taking advantage of mobile communication devices to coordinate surprise demonstrations. This tactics drew criticisms from several commentators who compared BART actions to what was typical of Middle East despots. Most people wondered whether interference with cell phone service does not amount to an unconstitutional infringement on citizens’ rights to free speech. Lackert (2013) agreed that while the BART station shutdown

was proper to protect public order, the unilateral action raised significant legal questions as to whether this was authorized under the US telecommunications law relating to passengers’ right to access telephone networks and the legality of a shutdown by a quasi-governmental authority (p. 577). Hence, smartphones and social networking platforms have been recognized globally as having heightened the provision of greater capability of people to organize and implement protests quickly via text, Twitter, and Facebook and non-Internet based cell phones. Countries where the Internet was shut down, as in Egypt, the only means of communication was through the existing telephone systems; this service was not easily or centrally controlled by Internet servers. This is why governments and institutions across the political spectrum have become alarmed at this development, and have struggled to give varying weights to public expression in relation to public order.

CURRENT SCIENTIFIC KNOWLEDGE

The first major work that articulates mobile phone’s collective actions is by Dr. Howard Rheingold, an expert and leading researcher in digital media at the University of California, Berkeley. His book: *Smart Mobs: The Next Social Revolution* (2002) is an important and comprehensive account of mobile phone use in contemporary activism. Rheingold explores the growing importance of “smart mobs” (also referred to as “mobile ad hoc networks”) in civil collective action. Citing the cases of the WTO (anti-globalization) protests in Seattle in 1999, and the “people power 11” protests in the Philippines that ousted Joseph Estrada in 2001, he suggests that the prevalence of smart phone and its influence is indeed responding to peoples’ need of cooperation amplified by ICTs (see also Mater, 2004; Monterde and Postill, 2013). Clay Shirky –a professor of New Media at New York University gives a detailed and interesting account of the power of text messaging in the Philippines protests of 2001. In his “the

political power of social media,” he recounts: “on January 17, 2001, during the impeachment trial of Philippine President Joseph Estrada, loyalists in the Philippine Congress voted to set aside key evidence against him. Less than two hours after the decision was announced, thousands of Filipinos, angry that their corrupt president might be let off the hook, converged on *Epifanio de los Santos Avenue*, a major crossroads in Manila. The protest was arranged, in part, by forwarded text messages reading, “Go 2 EDSA. Wear blk.” The crowd quickly swelled, and in the next few days, over a million people arrived, choking traffic in downtown Manila. The public’s ability to coordinate such a massive and rapid response - close to seven million text messages were sent that week - so alarmed the country’s legislators that they reversed course and allowed the evidence to be presented. Estrada’s fate was sealed; by January 20, he was gone. The event marked the first time that social media had helped force out a national leader. Estrada himself blamed ‘the text-messaging generation’ for his downfall...” (p.1). Similarly, Professor Shirky, in his landmark publication: *Here Comes Everybody: The Power of Organizing without Organizations* (2008), establishes the potentials of mobile technologies for collective action arguing that they promote the rise of new forms of mass action by reducing the users’ investment in time and money.

Monterde & Postill (2013) further gives interesting insights to the *uses of mobile phones for social protests by Spain’s indignados*, where text messages gave the Spaniards an “an alternative information channel” to the mainstream media, and like in Philippines, protesters “passed on” text messages that resulted in “unstoppable snowball effect,” (p.3). Jan H. Pierskalla at the German Institute of Global and Area Studies (GIGA) and Florian M. Hollenback at Duke University (2013) examine the roles of *technology and collective action and the effect of cell phone coverage on political violence in Africa* and argue that the spread of cell phone technology across Africa has transforming effects on the economic and political

sphere of the continent; and that the availability of cell phones allows political groups to overcome collective action problems more easily and improve in-group cooperation and coordination (p.1). A recent research has also tested the possible impact of mobile phones on voter information and participation, as well as its possible impact on fighting electoral fraud and corruption (see Aker, Collier, and Vincente 2011; Bailard 2009).

Beginning with the Arab spring, and social protests multiplying in western liberal democracies being confronted by financial crises and changes in welfare policies, more interesting studies are emerging with important findings on the effective roles of mobile telephony and web 2.0 in the protests. Kavanaugh et al (2011) give important insights to the functions of text messages in the Iran, Tunisian and Egyptian revolutionary protests, where SMS messages were not completely shut down (as in Iran 2006), because subscribers could easily be identified and possibly arrested. In Egypt, it was not technically difficult to disrupt mobile phone service as the Egyptian government did in one of the days of the protests; they simply ordered the Egyptian operator (ECMS) to shut off service, especially in the main demonstration areas of Cairo and Alexandria. Mobile phone signals were patchy and text messages inoperative (p.9). Tufekci & Wilson (2012) further provide quantitative documentation of the role of texting in information gathering and discussions of the Egyptian protests that ousted Hosni Mubarak. According to the study, about 82% of respondents used mobile phones to communicate about the protests in Egypt, with 62% texting; while 51% used Facebook. It further demonstrates that events in North Africa and the Arab world were being shaped by a new system of political communication which sets into sharp relief the importance of digitally mediated interpersonal communication, characterized by the increasingly interrelated use of satellite television, social media platforms and the widespread use of Internet-enabled cellphones capable of transmitting photos and video (p.375). This study further illustrates how elements of this

system contributed to lowering the costs of initiating and coordinating collective action to topple longstanding repressive regimes. It concludes that the high degree of adoption of digital communication in digital activism, illustrates how citizens overcome the potential risks of online activism in authoritarian regimes (Tufekci & Wilson, 2012).

Ever before the Egyptian uprising, Sean Jacobs and Diana Duarte writing for *Afronline news* had reported the “bread riots,” in Mozambique chronicling the power of SMS. According to the report, residents of the capital, Maputo, took to the streets having been prompted by text messages that told them to “enjoy the great day of the strike” and to “protest the increase in energy, water, mini-bus taxi and bread prices.” The government had insisted that the increases in price were not reversible. But days later, under pressure from rapidly SMS-organized protests, the government reconsidered their position and the old bread prices returned. And as a sign of its impact, the government, allegedly ordered cell phone service providers to briefly suspend text messaging for its users. Journalists that covered the protests as well as commented on social media were surprised at the power of SMS in a small African country where twice as many Mozambicans have cell phones as they have access to electricity. Opinion speculated about expanded opportunities for political engagement in developing countries (Jacobs & Duarte (2010:1).

Similarly the “occupy Nigeria” protests of January, 2012 was organized and implemented largely by the adoption of social media and text-messaging. The study concludes that with the growing Internet literacy and common use of mobile phones in Nigeria, many youths have also been increasingly aggressive in the use of social media and mobile telephony to engage in sociopolitical debates and critique government actions. Moreover, there is no ruling out the possibility that many Nigerian online activists are gradually more in touch with their counterparts in North Africa or elsewhere (Chiluwa, 2015).

Recounting, the Gezi Park uprising in Turkey in 2013, Yusuf Sarfati (2015), discovers that social

media and text messaging not only mobilized protesters, they also became “a tool for counter-mobilization” because “the well-organized supporters of Turkey’s governing JDP were quick in responding to the protesters and circulating counterframes to both national and international target audiences. This shows that social media can be a potential tool in organizing protests against the state, but can also be used by the state and its allies to diffuse or discredit protests,” (p.29). The Gezi Park protests began on May 30, 2013, when a group of environmentalists disagreed with the proposed uprooting of trees in Gezi Park at the city centre in Istanbul by the municipal authorities. The Municipal council began to implement its plan to burn down the park and build in its place a replica of an Ottoman era military barrack. Protesters were manhandled by the municipal police and tents of the camping protesters in Gezi Park were burnt down. When the images of wounded protesters were transmitted via social media and text messages, more enraged protesters gathered at the Taksim square adjacent to Gezi Park and in few days, the protest movement had been transformed into a national uprising against the government, mobilizing million all around Turkey. The riot police used tear gas, water cannons and pepper spray to disperse protesters (Sarfati, 2015, p.25). The use of texting and twitter as counter-mobilization strategy, especially for explaining the policy and activities of government is significant here, not only in Turkey but also in Nigeria, where the former President Jonathan and the current Senate President (Bukola Saraki), use twitter and sometimes, SMS to explain government positions and mobilize supports.

FUTURE RESEARCH DIRECTIONS

Shanthi Kalathil and Taylor Boas in their very popular and insightful book: *Open Networks, Closed Regimes* (2003) re-examine the use of the Internet and ICT-based communications in social protests, and argue that the impact of social media

and mobile phones towards effecting political change has actually been exaggerated. Based on an empirical assessment of evidence from China, Cuba, Singapore, Vietnam, Burma, the UAE, Saudi Arabia and Egypt, they contend that the Internet is indeed not a threat to authoritarian regimes. According to Morodov (2011) the assumed emancipator potential of new media technologies in social protests, actually strengthens the surveillance capabilities of repressive regimes. Shirky (2011) also doubts the effectiveness of information technology in organizing protests and argues that repressive governments are becoming better users of electronic tools to suppress dissents. These and a few other studies have brought to the fore the question: “does the internet and mobile telephony really achieve any significant political change?” In my opinion, this question should further provide future directions in research on the role of modern ICTs in sociopolitical change. In his epoch-making work: *The Net Delusion: the Dark Side of Internet Freedom* (2011), Evgeny Morodov – a visiting scholar at Stanford University, and a Schwartz fellow at the New America Foundation, argues that “cyber utopia” (i.e. the assumption that the Internet is liberator of the masses), is erroneous, because it leads to a conclusion that texting and social media can be used to bring down authoritarian governments and advance democracy. He advises that rather, the American people should shun their belief in cyber utopianism and acknowledge the downside of online communications. He believes that the public should come to terms with “net delusions” and implement a policy of cyber realism in order to achieve their political goals. While acknowledging the positive impact of social media in facilitating mobilization by reducing barriers to collective action, Bridwell (2013) further argues that online-based actions and mobilizations can work in non-democratic regimes. Hence, the advantages of social media and ICTs are especially suited to mobilizing in non-democracies. “In a democracy, the particular advantages of social media are more redundant, even if its tools offer improvements for mobiliz-

ers. Moreover, the negative qualities of social media cited by skeptics are more likely to hold in a democratic context” (p.3). Factors such as how gender and economics can affect access to new technologies should also be taken into consideration in assessing the utility of social media in protests (Christensen, 2011).

Arguably, texting and social media have been instrumental in mobilizing protesters and effecting political change in places like Tunisia, Egypt, and Libya. But the results are different in Bahrain, Syria, Turkey and Ukraine. In the Nigerian fuel subsidy protests, the protests failed to achieve their purpose because demonstrators were divided along ethnic lines. Some protesters also pledged their loyalty to different political parties; thus, while protesters were mobilized by the new ICTs, the offline protesters were not united in purpose. Citing the uprisings in Iran and Bangkok, Shirky (2011) also notes that the June 2009 protests by the Green Movement in Iran were a failure because, while the activists used every possible technology available to them to coordinate the protest against electoral misconduct, they were dispersed by a violent government crackdown. The Red Shirt uprising in Thailand in 2010 was similarly dealt with by the Thai government although protesters were well mobilized with the help of the social media. Many of the protesters even lost their lives.

CONCLUSION

Despite the skepticism among scholars about the effectiveness of ICT technology in achieving an impactful social change, a recent study by a women advocacy group, believes that an exclusive use of mobile phone and SMS will promote women activist efforts and reduce gang violence against women. In her position paper titled: “Mobilizing Change in Central America: Fostering Women’s Networks to Combat Gang Violence, (2016),” Emily S. Wasek of the *Institute for the Theory and Practice of International Relations at The College of William and Mary*, Virginia argues

that “despite women’s restricted movement within gang territories, cell phone technology can provide Central American women with a form of ‘immobile mobility’ that surpasses physical and cultural boundaries... With mobile phone technology, activists are able to more easily coordinate mass movements through the potentially viral effects of forwarding messages. Thus, access to mobile phones can help Central American women safely create anti-gang political violence.” She therefore called on the United States government to “encourage the development of women’s political networks through the use of mobile phone technology. In so doing, policymakers can both empower marginalized Central American women and enhance current policies aimed at disrupting gang activities” (Wasek, 2016, p.5).

It is clear therefore that texting via SMS has come to stay and have formed significant part of our daily living; and it is impossible to deny its effect and influence in persuasive communication. Whether immediate or on the long run, the results of activism and protests orchestrated by the social media and text messaging are significant. However, I still believe that it is important that researchers take a more cursory look at different political contexts and some unique nature of protests in order to properly assess the impact of the Internet and mobile telephone in social change

KEY TERMS AND DEFINITIONS

Computer-Mediated Communication (CMC): Communication that takes place through the use of electronic devices, usually by individuals who are connected either online or a network connection using social software and interact with each other via separate computers.

Mobile Phone (or Cell Phone): A device that can make and receive telephone calls over a radio link, while moving around a wide geographical area. This is possible by connecting to a cellular network provided by a mobile phone operator, allowing access to the public telephone network (see *Wikipedia*, 2013).

Mobile Technology: Technology used for cellular communications.

Protest: The expression of objection by protesters through words or actions or other forms of social behavior that rejects or resists certain government policies, or the existing sociopolitical structures.

Protester: Someone engaged in a protest.

SMS: 'Short message service' is text messaging service component of the mobile phone, web or mobile communication systems.

Social Media: The interaction among people in which they create, share, and/or exchange information and ideas in virtual communities and networks (see Ahlqvist et al 2008); or 'a group of internet-based applications that build on the ideological and technological foundations of *Web 2.0* and that allow the creation and exchange of usergenerated content (see Kaplan & Haenlein 2010).

M

A Survey of People Localization Techniques Utilizing Mobile Phones

Levent Bayındır

Ataturk University, Turkey

INTRODUCTION

With the ongoing diffusion of mobile computing and context-aware applications, knowledge of the current location of an individual can be leveraged in a number of different domains, from personal diaries and fitness-related applications to human behavior analysis and targeted advertising.

Mobile phones are routinely carried by their owner during daily activities, and the embedded sensors commonly found in modern devices can be used to capture data of interest from the area surrounding an individual; these data can then be processed to estimate the current location of the phone user.

Two different categories of localization studies can be identified: indoor/outdoor detection and indoor localization. In the first category, the aim is to differentiate between indoor and outdoor areas, while the second category comprises all the studies addressing the challenges encountered in identifying the location of a person in an indoor environment, where the majority of people spend most of their time, and where the technology typically used for outdoor localization (i.e. satellite-based positioning) is generally not available.

The capability to automatically differentiate between indoor and outdoor environments can be used for example to enable an efficient use of power-hungry sensors such as GPS receivers, possibly selecting alternative localization methods while indoors; applications that recognize and analyze human activities can leverage indoor/outdoor detection for improved accuracy, given that many activities can only be executed either in

indoor environments or outdoors; other examples of possible uses are automatic image annotation when a picture is taken with a smartphone, or adaptation of phone settings to the current environment type (e.g. increasing ringer and notification sound volume when outdoors).

A typical use of indoor localization techniques is for personal navigation, especially useful in large buildings such as shopping malls, hospitals, airport terminals, university campuses, or office buildings; more advanced uses are made possible by the proliferation of mobile apps that can leverage location information: for example, a museum visitor can access detailed information about the nearby items on display; a customer in a grocery store can search for a specific product and easily reach the aisle where the product is located; other applications allow precise tracking of people in need of care, such as children, elders or disabled people. In addition, human activity classification algorithms can greatly benefit from knowledge of the physical location of an individual, since in many cases location is highly correlated to the activity being carried out (e.g. sleeping is typically done in the bedroom, and cooking in the kitchen).

This article presents a review of past research works describing techniques for utilizing smartphone sensors to identify the environment where a smartphone user is located. The review focuses on studies where user location can be computed autonomously and continuously by a smartphone, without the need for an active involvement of the user, and where issues such as power consumption and dependence of sensor readings from the on-body position of the phone are addressed.

BACKGROUND

In the last few decades there has been an increasing interest in positioning technologies. The deployment of a number of satellites in the Earth's orbit enabled satellite-based positioning, whose main use case was vehicle navigation, but due to poor performance of this technology in indoor areas, indoor location methods have to rely on other means. The first indoor location techniques required carrying specialized devices and/or deploying ad-hoc hardware in the environment; then, the continuous enhancement of mobile phone sensing and computation capabilities, and the widespread deployment of infrastructure for wireless communication opened new frontiers for indoor localization; now, an increasing number of location-based services are made possible by different technologies for locating people in indoor environments.

Many pervasive computing applications are enabled or can be enhanced by knowledge of the current *user context*; while the exact definition of user context can vary between applications, physical location is an important piece of information in defining the context for many applications. Thus, methods for automatic localization of users can be considered as part of the more general issue of user context recognition (Hoseini-Tabatabaei, Gluhak, & Tafazolli, 2013).

Virtually all sensors and communication interfaces embedded in modern smartphones can be used for localization: receivers for wireless technologies such as GSM, GPS, Wi-Fi, Bluetooth, and even FM radio can detect and identify existing infrastructure such as cell towers or Wi-Fi access points; inertial and orientation sensors can detect physical movements and orientation changes of the phone, and thus their readings can be correlated to movements of the phone user; other sensors can capture characteristics of the surrounding environment from which useful information for localization can be extracted.

Two basic methods can be identified in most indoor localization applications: fingerprinting

and dead reckoning (Subbu, Zhang, Luo, & Vasilaikos, 2014). These two methods, which can be used alone or in combination, utilize sensor readings to detect local characteristics of the environment or movements of a mobile device, and are often complemented by additional techniques (Yang et al., 2015) to overcome their inherent limitations and improve localization performance: Shang, Hu, Gu, Wang, & Yu (2015) identified three categories of methods that fuse sensor readings with *spatial contexts*: map matching, landmark fusion, and spatial model-aided methods.

Figure 1 provides a taxonomy for the different studies on indoor/outdoor detection and indoor localization reviewed in this article.

INDOOR/OUTDOOR DETECTION

In a number of recent research studies dealing with environment detection, the focus is on discriminating between indoor and outdoor environments. Since all smartphones are equipped with cameras, among the different methods that can be implemented in a smartphone to detect the environment type there are vision-based methods that analyze images captured from the camera to extract features useful for scene understanding. These techniques, which have been studied extensively even before the advent of smartphones, will not be reviewed here, since when implemented in a smartphone they usually require active user involvement to capture the scenes of interest, and are not applicable in most situations where the mobile device is worn randomly by the user.

General unavailability of satellite coverage for navigation purposes in indoor areas can be used to infer indoor/outdoor location. For example, Hermann, Zappi, & Rosing (2012) and Ravindranath, Newport, Balakrishnan, & Madden (2011) used the inability to obtain a GPS location as a hint that the user is indoors; in Cho, Song, Park, & Hwang (2014), from identification of visible satellites and information on their current position in the Earth orbit, the directions on which there is a clear

Figure 1. Taxonomy of people localization techniques utilizing mobile phones

view of the sky, and conversely the directions on which the view of the sky is obstructed, are identified, and this information is used to classify the environment type as indoors or outdoors. Other researchers combined observation of GPS signals with other wireless signals that have different characteristics in different environment types: Pei et al. (2013) used the strength of Wi-Fi and GPS signals to derive a measure of the probability of being indoors or outdoors; Parviainen, Bojja, Collin, Leppänen, & Eronen (2014) extracted a set of features from Wi-Fi, GPS and Bluetooth signals, and used them as input to a binary indoor/outdoor classifier; Anagnostopoulos & Deriaz (2015) based their method on estimation of the accuracy of two complementary localization techniques (GPS-based and Bluetooth-based).

Since the GPS receiver is a major source of power consumption, many researchers studied methods to avoid utilizing this sensor in indoor

areas (in fact, this is one of the motivations for indoor/outdoor detection studies): for example, in the Wi-Fi-based indoor navigation system by Gallagher, Li, Dempster, & Rizos (2011), Wi-Fi networks near the entrances of a building are marked as “transition zones”, and the GPS receiver of the mobile phone is turned on only when located in such transition zones; Soria Morillo, Ortega Ramírez, Alvarez García, & Gonzalez-Abril (2012) developed a method to automatically learn the pattern of Wi-Fi signals observed when entering a building, so that when a similar pattern is observed at a later time the system can infer a transition to an outdoor area; Zou et al. (2016) deployed a set of fixed Bluetooth devices in semi-outdoor areas so that a mobile phone can infer a transition between indoors and outdoors when these devices are sensed by the Bluetooth receiver. In Chen, Sivaraman, Das, Ravindranath, & Balakrishnan (2015), Wi-Fi signal strength is

used as input to a binary classifier for indoor/outdoor detection.

Usually, measurement of wireless signals by a mobile phone incurs a relatively high cost in additional energy consumption (a notable exception is given by cell tower signals, because the relevant radio receiver in the phone is always powered on for proper phone operation); for this reason, some studies focused on utilizing for indoor/outdoor detection more battery-friendly sensors, which can capture other characteristics that can help in differentiating between indoor and outdoor environments. One of these characteristics is given by the magnetic field, which due to the presence of electric appliances and steel structures is typically subject to high variations inside buildings; other characteristics, such as light intensity and temperature, are purposely modified by people indoors in order to reach desired comfort levels. These ambient characteristics can be acquired by low-power sensors in modern smartphones, and as such can be used for power-efficient indoor/outdoor detection algorithms (Nakamura, Ono, Sekiya, Honda, & Takahashi, 2015; Radu, Katsikouli, Sarkar, & Marina, 2014; Zhou, Zheng, Z. Li, M. Li, & Shen, 2012).

INDOOR LOCALIZATION

Dead reckoning methods have been extensively studied for localization in indoor areas; more specifically, pedestrian dead reckoning (PDR) refers to dead reckoning techniques explicitly modeling movement of pedestrians as a sequence of discrete walking steps, and thus calculating the displacement of a pedestrian via step detection, heading estimation and step length estimation. While step detection can be implemented relatively easily in smartphones equipped with an accelerometer, heading estimation is generally more difficult, due to the fact that phone orientation can be different from user orientation, and the presence in most indoor settings of high magnetic field disturbances is a major source of noise in magnetometer readings;

some of the techniques that have been adopted to address this issue involve using the gyroscope to complement noisy compass readings, and applying Principal Component Analysis to the acceleration signal (Deng, Wang, Hu, & Wu, 2015; Mohssen, Momtaz, Aly, & Youssef, 2014), based on the fact that the walking direction usually corresponds to the direction of maximum acceleration variance.

Signal fingerprinting is a localization method that exploits the presence in the environment of electromagnetic signals that change depending on the physical location. The most used signals for this purpose are the signals emitted by Wi-Fi access points, which are ubiquitously used in modern buildings to provide wireless network connectivity. Practical application of fingerprinting is made difficult by factors such as an irregular signal propagation pattern in indoor environments and the dependence of signal reception in a mobile device from the on-body position and orientation of the device; in various studies, different methods have been envisaged to deal with these issues: for example, in Sánchez-Rodríguez, Hernández-Morera, Quinteiro, & Alonso-González (2015), Wi-Fi signal strength values in the fingerprint database are combined with phone orientation information. Another disadvantage of fingerprinting methods is the need to build the fingerprint database, often by means of time-consuming site surveys; to mitigate this problem, Bisio et al. (2014) suggested the use of modeling and analytical estimation of wireless signal propagation instead of site surveys.

In addition to Wi-Fi, other types of signals have been investigated for fingerprinting: for example, magnetic field fingerprinting takes advantage of the presence of magnetic field anomalies inside buildings (Carrillo, Moreno, Úbeda, & Skarmeta, 2015; Zhang, Luo, & Wu, 2014); GSM fingerprinting leverages the presence of the cell towers used for mobile communications (Li, Bigham, Bodanese, & Tokarchuk, 2013); FM radio broadcast signals are another source of information that lends itself to fingerprinting (Chen, Lymberopoulos, Liu, & Priyantha, 2012; Moghtadaiee & Dempster, 2014; Yoon, Lee, &

Rhee, 2013). All these alternative signals can be used alone or in combination with Wi-Fi to improve localization performance.

Some studies investigated the use of PDR and fingerprinting methods combined; the most used techniques for fusing the two methods are Kalman filtering (G. Chen et al., 2015; Z. Chen et al., 2015; Deng, Hu, Yu, & Na, 2015; Faragher & Harle, 2013) and particle filtering (Hilsenbeck, Bobkov, Schroth, Huitl, & Steinbach, 2014; Shu et al., 2015). Other researchers (He, Chan, Yu, & Liu, 2015; Li et al., 2015) found that fingerprinting can be combined and take advantage of simple step detection methods, without explicitly calculating the heading direction of a pedestrian.

An inherent disadvantage of using a relative positioning method such as PDR is its tendency to accumulate the localization error over time; map matching techniques can help to solve this problem by adjusting location estimates according to a map of the indoor environment. Various map matching algorithms have been investigated, such as graph-based methods (Shih & Lan, 2012), particle filtering (Li et al., 2012; Qian, Pei, Ma, Ying, & Liu, 2015; Shang, Gu, Hu, & Kealy, 2015), Hidden Markov Models (Zhou, Li, Mao, Tu, & Zhang, 2015) and Conditional Random Fields (Xiao, Wen, Markham, & Trigoni, 2014).

Fingerprinting and map matching methods require the presence of a map of the indoor environment, and this is a potential problem because it may not be convenient to create or have access to updated maps for any indoor environment a user visits. To address this issue, simultaneous localization and mapping (SLAM) methods have been developed. SLAM is based on the principle that local characteristics of the environment can be dynamically learned and recognized as a place is visited multiple times. Different types of such characteristics have been studied, and Wi-Fi signals are probably the most used information source: the sequence of Wi-Fi measurements while a user walks in an indoor environment can be recorded and compared with data stored from previous visits, allowing the system to build a

model of the indoor space and to learn the adjacency between different parts of a building (M. Zhou et al., 2015). Learning the indoor layout is often facilitated by using PDR (Luo, Hong, & Chan, 2014), which can improve the accuracy of estimating the spatial relationship between different Wi-Fi measurements. Instead of implementing a full dead reckoning algorithm, other researchers (Wu, Yang, & Liu, 2015) estimated (via step detection) only the distance walked between successive measurements, while in other studies (Jiang et al., 2013) a simple motion sensing algorithm is used.

SLAM methods often utilize landmarks of the environment to facilitate the mapping process: such landmarks can be detected as a consequence of a mobile user moving in specific locations in the environment, like the inertial-based anchor points in Alzantot and Youssef (2012), or can be manually placed objects such as NFC tags (Mirowski, Ho, Yi, & MacDonald, 2013); in Zhang, Subbu, Luo, & Wu (2015), landmarks can be detected in correspondence of turns in walking paths, and can also be added manually by users by annotating the indoor map. Analogously to what happens when people learn how to navigate a new place, if known landmarks are sensed in a localization application an imprecise location estimate can be corrected.

FUTURE RESEARCH DIRECTIONS

The multitude of indoor localization techniques developed in recent years is filling the gap between indoor and outdoor localization; with the widespread use of Wi-Fi networks and the possibility of automatically building and updating indoor maps via crowdsourcing, internet-based navigation (Zeinalipour-Yazti, Laoudias, Georgiou, & Chatzimilioudis, 2016) has the potential to enable seamless transition between indoor and outdoor environments with continuous localization services.

As mentioned earlier, physical location represents only part of the context where users are located, and other characteristics of the environ-

ment are often equally important in defining the context. Methods for automatic environment classification (for example, to identify places such as restaurants, pubs, cafes, offices, homes, streets, parks, etc.) and high-level semantics annotation are already being researched (Ali, Basalamah, & Youssef, 2014; Parviainen, Bojja, Collin, Lepänen, & Eronen, 2014), and it can be expected that these methods will be further improved in the near future, to provide pervasive computing applications a user context including high-level semantic information.

CONCLUSION

This article reviewed the state of the art of localization techniques used in applications that can run on mobile phones; more specifically, two areas of interest have been identified: studies aiming at differentiating between indoor and outdoor environments, and studies tackling the issue of localization in indoors areas, where satellite-based positioning services are generally unavailable. Due to the presence of a large body of research (especially on the topic of indoor localization), the review has been limited to recent publications, which build upon research conducted in previous years and exploit technological advances in modern smartphones.
